

Value Emergence Record Module (VERM)

Value Emergence Record Module (VERM)

Architecture Ecosystem: Structured Reality Standards™
Architecture Family: VFM® — Value Flow Mechanisms Architecture
Parent Standard: Value Emergence Standard (VES)
Module: VERM — Value Emergence Record Module
Operational Layer: Value Emergence Record Layer
Category: Governance & Enforcement
Subcategory: Value Lifecycle Governance
Type: Core Module
Governed Space: Value Emergence Record
Origin ID: VFM-VES-VERM-003.5
Version: 1.0
Status: Canonical · Open Standard
Effective Date: 24 August 2026
Compatibility: OOF® Methodology OS™ · GOA™ · ORA™ · INTEGROS® · CLA™ · ADIT® · VALIDOS® · SIMULOS® · OBIDENITY®
AI-Readable: Yes

Authority: OOF®
Protection: MIP® — Methodology Intellectual Property Protection
Canonical Language: UCL — Universal Canonical Language

Canonical Definition

Value Emergence Record Module (VERM) is the fifth Core Module of the Value Emergence Standard (VES) within VFM® — Value Flow Mechanisms Architecture.

VERM governs the formal recording, preservation, traceability, contextualization, versioning, and lifecycle transfer of a Value Emergence Determination after the emergence process has been assessed through the preceding modules.

Its purpose is to ensure that a determination that value has emerged, has not emerged, has emerged conditionally, remains indeterminate, or has been superseded does not survive merely as an isolated statement.

VERM preserves the governed relationship:

What Value → From What Origin → Under What Context → Under What Conditions → At What Threshold → Through What Event → On What Determination Basis → At What Time → With What Scope and Limitations → With What Emergence State

VERM therefore converts the result of Value Emergence governance into a persistent and reconstructable Value Emergence Record capable of entering the next stage of the VFM® lifecycle.

Architectural Position

VERM is the fifth and final module within the Value Emergence Standard.

It follows:

VEDM — Value Emergence Determination Module

and completes the internal Value Emergence sequence:

Emergence Conditions → Emergence Threshold → Emergence Event → Emergence Determination → Emergence Record

The internal module roles are:

VECM establishes the conditions under which value may emerge.

VETM establishes the threshold separating potential value from existent value.

VEEM identifies the event or event structure associated with crossing that boundary.

VEDM determines whether the governed value has actually emerged.

VERM preserves that determination and its governing basis for subsequent lifecycle use.

VERM is therefore the persistence and transfer layer of Value Emergence.

Governance Flow Position

Within the complete VFM® governance flow:

Value Context → Value Origin → Value Emergence → Value Recognition → Value State → Value Change → Value Development / Value Degradation

→ Value Nullification → Value Restoration / Value Extinction

VERM operates at the final boundary of:

Value Emergence

immediately before:

Value Recognition.

Its architectural role is critical because the next standard must not receive merely an assertion that:

“value exists.”

It should receive a governed record explaining which value exists, why its emergence was determined, under what conditions that determination applies, and what limitations remain attached to it.

Internal Value Flow

Potential Value → Emergence Conditions → Emergence Threshold → Emergence Event → Emergence Determination → Determination State → Record Assembly → Context Linkage → Origin Linkage → Conditions / Threshold / Event Linkage → Determination Basis Preservation → Scope & Limitation Preservation → Temporal Anchoring → Record Versioning → Value Emergence Record → Value Recognition Governance

This establishes a controlled lifecycle transition:

Emergence Determination → Governed Emergence Record → Recognition Candidate

Operational Purpose

Value claims frequently become detached from the conditions that originally supported them.

An organization may initially determine:

“This capability created value under these conditions.”

Months or years later, the surviving organizational statement may become simply:

“This capability has value.”

The original:

beneficiary; context; threshold; evidence; assumptions; timing; limitations; uncertainty;

configuration; determination basis

may disappear.

VERM exists to prevent this loss of methodological meaning.

The record preserves enough information to reconstruct:

what was determined

and

why that determination was legitimate at the time it was made.

Value Emergence Record

A Value Emergence Record is the governed representation of a Value Emergence Determination together with the material lifecycle information required to interpret that determination correctly.

At minimum, a record should be capable of identifying:

1. the governed value; 2. the relevant Value Context; 3. the Value Origin; 4. applicable emergence conditions; 5. applicable emergence threshold; 6. qualifying emergence event; 7. emergence determination; 8. determination state; 9. determination basis; 10. effective emergence time; 11. determination time; 12. applicable scope; 13. beneficiary where relevant; 14. material limitations; 15. material uncertainty; 16. record version; 17. subsequent changes or supersession.

The exact implementation may vary according to the value domain.

The governance requirement does not.

Record ≠ Determination

VERM maintains a strict distinction:

Value Emergence Determination ≠ Value Emergence Record

VEDM determines whether value emerged.

VERM records that determination and preserves the conditions that give it meaning.

A record must not silently change the underlying determination.

If a determination requires reassessment, that reassessment belongs in the governed determination process.

VERM then records the resulting new state.

Record ≠ Evidence

A Value Emergence Record may contain references to evidence.

It is not itself equivalent to all underlying evidence.

The record may preserve:

evidence identifiers; evidence references; evidence summaries; evidence relationships; evidence states; determination basis.

Underlying evidence may remain governed by the relevant evidence, integrity, audit, validation, operational, or external systems.

Therefore:

Record of Evidence $\neq$ Evidence Itself

and

Value Emergence Record $\neq$ Universal Evidence Repository.

Record Identity

Every material Value Emergence Record should be independently identifiable.

Record identity may include:

Record ID; governed value identifier; Value Context reference; Value Origin reference; Value Emergence Determination reference; version; status; creation time; effective time.

This enables multiple emergence records to coexist without being silently merged.

Context Preservation

VERM must preserve the Value Context under which emergence was determined.

This is necessary because the same underlying object may create different forms of value for different:

beneficiaries; purposes; environments; periods; systems; relationships; reference frameworks.

A record stating only:

“Value emerged”

is insufficient where the value cannot be understood without its context.

VERM therefore preserves:

Value Emerged → For Whom → In Relation to What → For What Purpose → Under What Reference Context

where materially applicable.

Origin Preservation

The record should preserve the relationship between the emerged value and its governed Value Origin.

This allows later lifecycle analysis to distinguish:

the value

from

the source from which that value emerged.

The distinction is essential because one Value Origin may generate multiple values, and one governed value may depend upon multiple contributing origins.

Therefore:

Origin Asset™ ≠ Emerged Value.

VERM preserves the relationship without collapsing the two.

Condition Preservation

The emergence conditions established through VECM should remain linked to the record where materially relevant.

This allows later users to determine whether the value emerged:

only under specific conditions; under a defined configuration; for a particular beneficiary; during a specific operational state; after a defined capability became available; only when multiple conditions converged.

Without this information, downstream systems may incorrectly generalize the value.

Threshold Preservation

VERM should preserve the emergence threshold that separated:

Potential Value

from:

Existing Value.

The record should make it possible to understand what threshold was crossed and why that crossing was considered sufficient.

This is particularly important where later review asks:

Why was value considered to exist at this point rather than earlier or later?

Emergence Event Preservation

Where an identifiable emergence event or composite event exists, VERM should preserve its relationship to the record.

Relevant information may include:

event identity; event type; event time; event sequence; event conditions; event relationship to threshold crossing; event relationship to the governed value.

The record does not need to reproduce the complete operational event history.

It preserves the event relationship necessary to reconstruct value emergence.

Determination Basis Preservation

VERM must preserve the basis supporting the emergence determination.

The basis may include references to:

observed outcomes; measurements; operational evidence; simulation evidence; financial evidence; scientific evidence; capability evidence; beneficiary effects; performance results; threshold evidence; contextual evidence; contradictory evidence; uncertainty.

VERM does not independently validate every source.

It preserves the basis upon which the determination was made.

Temporal Anchoring

Value emergence has more than one relevant time.

VERM should distinguish where applicable:

Value Origin Time

Emergence Condition Satisfaction Time

Threshold Crossing Time

Emergence Event Time

Value Emergence Effective Time

Emergence Determination Time

Record Creation Time

These timestamps may be identical.

They may also differ substantially.

Preserving them allows later systems to reconstruct the lifecycle without forcing one artificial timestamp onto multiple distinct events.

Retroactive Emergence Record

Where VEDM establishes retroactively that value emerged at an earlier time, VERM should preserve both:

Emergence Effective Time: T1

and

Determination / Record Time: T2.

This distinction can be important for:

investment evaluation; project assessment; public expenditure analysis; accounting interfaces; economic measurement; infrastructure governance; intellectual property; future tax-governance interfaces; historical value reconstruction.

VERM records the temporal relationship without itself determining legal or accounting consequences.

Record Scope

Every Value Emergence Record must remain bounded by the scope of the determination it represents.

Scope may include:

value type; beneficiary; object; capability; jurisdictional context; operational context; purpose; configuration; period; environment; value dimension.

A narrow determination must produce a narrow record.

VERM must not convert:

Value Emerged for Beneficiary A under Condition B

into:

Value Exists Universally.

Conditional Emergence Record

Where VEDM establishes:

Conditionally Emerged

VERM must preserve those conditions as part of the record.

The conditions are not optional annotations.

They are part of the meaning of the emergence state.

A conditional record that loses its conditions becomes methodologically misleading.

Partial Emergence Record

Where only part of a governed value structure has emerged, VERM may preserve:

emerged component; non-emerged component; component relationship; partial emergence state; remaining emergence requirements.

This enables downstream governance to distinguish:

partially emerged value

from

fully emerged value.

Composite Emergence Record

Complex value may depend upon several constituent components or emergence pathways.

VERM may therefore preserve composite structures such as:

Component A → Emerged

Component B → Emerged

Component C → Conditionally Emerged

Composite Value → Emergence Not Yet Fully Established

This is useful for infrastructure, banking, industrial systems, AI, research programs, mission systems, supply chains, public investment, and other complex value structures.

Uncertainty Preservation

Material uncertainty associated with the Value Emergence Determination must remain attached to the record.

The record should distinguish where possible between uncertainty concerning:

whether value exists; how much value exists; scope of value; beneficiary effect; duration; future persistence; causal contribution; supporting evidence.

A record should not create greater certainty than the underlying determination possessed.

Contradiction Preservation

Material contradictory information considered during the determination should not disappear from the record merely because a positive emergence determination was issued.

Where relevant, VERM may preserve:

contradiction identifier; contradiction type; effect on determination; unresolved issue; reason the determination remained supportable; reassessment trigger.

This prevents downstream users from seeing only the favorable basis.

Record Versioning

A Value Emergence Record may evolve.

VERM therefore requires controlled versioning where material changes occur.

A later version should not silently overwrite the historical record.

Possible states may include:

Active

Under Review

Amended

Superseded

Withdrawn

Archived

The applicable implementation may vary, but the lifecycle history should remain reconstructable.

Supersession

A new Value Emergence Determination may supersede an earlier determination.

VERM should preserve:

Previous Record → Superseding Record

rather than deleting the previous state.

This makes it possible to reconstruct:

what was believed; on what basis; when it changed; why it changed; which determination became authoritative afterward.

Record Correction

A factual or administrative error in a record may require correction without changing the underlying emergence determination.

VERM should distinguish:

Record Correction

from:

Determination Change.

For example, correcting an incorrect timestamp transcription does not necessarily require a new emergence determination.

Changing the conclusion from:

Emerged

to:

Emergence Not Established

does.

Record Integrity

VERM requires the record to remain sufficiently protected against uncontrolled alteration, loss of context, or ambiguous versioning.

However, VERM does not replace INTEGROS®.

The boundary is:

VERM: defines what emergence information must remain preserved and connected.

INTEGROS®: may govern the broader integrity properties of the record and supporting systems.

Record Auditability

VERM requires sufficient traceability for the emergence record to be reconstructed.

It does not own general audit governance.

ADIT® may govern:

audit observation; evidence preservation; verification; audit execution; findings; assurance.

Therefore:

Emergence Record Traceability ≠ Audit Governance.

Record ≠ Accounting Entry

A Value Emergence Record does not automatically create an accounting entry.

VFM® may determine:

Value Emerged

while accounting standards determine:

No Recognizable Accounting Asset Exists.

These outcomes are not inherently contradictory because they govern different questions.

VERM can provide a structured upstream value record that accounting systems may reference where appropriate.

Record ≠ Tax Record

A Value Emergence Record does not establish:

taxable income; taxable event; tax base; taxpayer; tax liability; jurisdiction; tax timing.

A future tax-governance architecture may consume VFM® records as inputs.

But:

Value Emergence Record ≠ Tax Assessment.

Record ≠ Ownership Record

VERM does not determine who owns the value or underlying object.

Where ownership, identity, authority, provenance, or transfer matters, the relevant governance may be supplied by OBIDENTITY® or other applicable systems.

Therefore:

Emergence Record ≠ Ownership Register.

Record ≠ Validation Certificate

A Value Emergence Record records the VFM® emergence determination.

It does not automatically establish a VALIDOS® Validation State.

A Value Emergence Record or the underlying emergence claim may itself become a Validation Object.

Therefore:

Recorded Value Emergence ≠ Validated Value Claim.

Recognition Interface

VERM creates the formal interface from:

Value Emergence

to:

Value Recognition.

The next lifecycle question is no longer:

Does the value exist?

That question has already been governed through VES.

The next question becomes:

Can this existing value be recognized as value within the defined governance context?

The transfer should therefore preserve:

Governed Value Identity

Value Context Value Origin Relationship Emergence State Emergence Effective Time Determination Basis Scope
Conditions Limitations

Uncertainty

This becomes the governed input to the Value Recognition Standard (VRS).

Recognition Candidate

Where emergence has been positively or conditionally established, VERM may produce a:

Value Recognition Candidate

A Value Recognition Candidate is not yet formally recognized value.

It is:

an existing value whose governed emergence basis is sufficiently recorded to enter Value Recognition governance.

This creates the lifecycle distinction:

Existing Value $\neq$ Recognized Value.

Machine-Readable Value History

VERM enables the value lifecycle to be represented as structured state history.

For example:

Value ID: V-2048

Origin State: Established

Potential Value State: Active

Emergence Threshold: Reached

Emergence Event: Recorded

Emergence Determination: Emerged

Effective Time: T1

Determination Time: T2

Emergence Record Version: 1.0

Next Lifecycle State: Recognition Candidate

This structure enables VFM® to become usable by:

enterprise systems;

AI governance systems; banking systems; investment platforms; public-sector systems; accounting interfaces;
economic measurement systems; industrial systems; digital asset infrastructures; future value-governance platforms.

Minimum Implementation Framework

A minimum VERM implementation should establish:

1. Record Identity

Create an independently identifiable Value Emergence Record.

2. Value Linkage

Link the record to the governed value established under the Value Context.

3. Origin Linkage

Preserve the relevant Value Origin relationship.

4. Emergence Basis

Preserve the applicable conditions, threshold, event, and determination basis.

5. Determination State

Record the formal emergence determination state.

6. Temporal Structure

Record relevant emergence, determination, and record times.

7. Scope and Conditions

Preserve the boundaries within which the determination applies.

8. Limitations and Uncertainty

Preserve material limitations, contradictions, and uncertainty.

9. Version Control

Maintain controlled amendment, correction, supersession, and historical continuity.

10. Lifecycle Transfer

Create the governed interface into Value Recognition where appropriate.

Governance Outputs

VERM may produce:

Value Emergence Record Value Emergence Record ID Value Emergence Traceability Chain Value Emergence Context
Link Value Origin Link Value Emergence Condition Record Value Emergence Threshold Record Value Emergence
Event Link Value Emergence Determination Link Value Emergence Effective-Time Record Value Emergence Scope
Record Value Emergence Limitation Record Value Emergence Uncertainty Record Value Emergence Contradiction
Link Value Emergence Version History Value Emergence Supersession Record Value Recognition Candidate

Together, these outputs close the governed Value Emergence lifecycle and create the structured input for Value Recognition.

Use Case 1 — Banking & Investment: Persistent

Proof of Where Value Actually Emerged

A bank finances a large industrial modernization program.

The borrower installs:

new production lines; automation; robotics; AI systems; energy infrastructure; digital control systems.

The program costs CHF 800 million.

Two years later, management states that the investment “created substantial value.”

Without a governed value record, analysts may need to reconstruct the claim from fragmented:

financial reports; project documentation; operational metrics; management statements; production records; technical reports.

VFM® instead preserves the lifecycle:

Value Context → Value Origin → Potential Value → Emergence Conditions → Emergence Threshold → Emergence Event → Emergence Determination

→ Value Emergence Record

Suppose the governed value is:

additional sustainable production capability of 400,000 units annually at a defined cost and quality threshold.

VERM records:

what capability emerged, when it emerged, under which operational configuration, what threshold was crossed, what evidence supported the determination, which limitations remained, and which version of the production system generated the value.

Years later, the bank can distinguish:

Capital Invested

from

Assets Installed

from

Value Emerged

from

Value Later Recognized

from

Value Subsequently Developed or Degraded.

This gives banking and investment systems something conventional project reporting often lacks:

a reconstructable lifecycle history of value itself.

Use Case 2 — Space Mission / AI: Preserving

Value Beyond Technical Success

A space agency deploys an AI navigation capability intended to increase scientific access during a planetary mission.

The mission generates thousands of technical and scientific records.

The AI operates successfully.

But the governed value is not merely:

AI System Activated.

The governed value is:

additional scientifically relevant mission access produced by autonomous navigation capability.

The emergence pathway establishes that the capability enabled the spacecraft to reach scientifically valuable locations that could not otherwise have been accessed within the mission constraints.

VEDM determines:

Value Emerged.

VERM then preserves:

which mission value emerged

from which capability

for which mission purpose

under which conditions

at which mission phase

through which emergence event

on what evidence basis

with what remaining uncertainty

and

within what scope the determination remains legitimate.

Years later, the organization can compare this record against subsequent missions.

It can determine whether the original value:

persisted; developed; degraded; was reproduced; became obsolete; was restored; disappeared.

The technical mission archive tells the organization:

what happened.

The VFM® Value Emergence Record tells it:

what value emerged from what happened.

Foundational Principles

A Value Emergence Determination without a persistent governed record is vulnerable to loss of meaning.

A record must preserve the context that gives the emergence determination meaning.

Value Emergence Record ≠ Value Emergence Determination.

Value Emergence Record ≠ Evidence Repository.

Value Emergence Record ≠ Accounting Entry.

Value Emergence Record ≠ Tax Assessment.

Value Emergence Record ≠ Ownership Register.

Value Emergence Record ≠ Validation Certificate.

Emergence Effective Time ≠ Determination Time ≠ Record Creation Time.

A narrow emergence determination must remain narrow when recorded.

Conditional emergence must remain conditional.

Uncertainty must not disappear when value is recorded.

Historical records must not be silently overwritten by later determinations.

Existing Value ≠ Recognized Value.

The record closes Value Emergence and opens the governed path into Value Recognition.

Canonical Closing Statement

Value Emergence Record Module establishes the persistence, traceability, temporal continuity, and lifecycle- transfer layer of the Value Emergence Standard by transforming a Value Emergence Determination into a governed and reconstructable Value Emergence Record. Through preservation of the governed value, Value Context, Value Origin, emergence conditions, threshold, event, determination basis, determination state, effective time, scope, limitations, contradictions, uncertainty, version history, and supersession relationships, VERM prevents value-existence claims from becoming detached from the conditions that originally gave them meaning. By distinguishing the emergence

record from evidence, accounting recognition, taxation, ownership, validation, and downstream Value Recognition, VERM preserves the architectural boundary of VFM® while enabling existing value to move through subsequent lifecycle stages without losing its origin or emergence history. VERM therefore completes the Value Emergence governance sequence and creates the persistent methodological bridge from Potential Value through established Existing Value to the next governed question: whether that existing value may legitimately become Recognized Value.
