Canonical Language: English

Canonical Definition

Value Origin Conditions Module (VOCM) is the fourth Core Module of the Value Origin Standard (VOS).

VOCM governs the conditions that must exist, remain satisfied, become activated, or interact for an established Value Source, Value Source Basis, and Value Origin Relationship to provide a legitimate pathway toward the emergence of the governed value.

The Module establishes the conditions under which a potential value-origin relationship becomes capable of producing or enabling value.

VOCM does not determine that value has already emerged.

It establishes whether the necessary origin conditions exist for the value-origin pathway to operate.

The distinction is fundamental:

Value Source ≠ Value Source Basis ≠ Value Origin Relationship ≠ Value Origin Conditions ≠ Existing Value

Architectural Position

VOCM is the fourth module within the Value Origin Standard.

It follows:

VORM — Value Origin Relationship Module

and precedes:

VODM — Value Origin Documentation Module.

The internal sequence is:

Identified Value Source → Established Value Source Basis → Established Value Origin Relationship → Origin Condition Identification → Condition Classification → Condition Dependency Assessment → Condition State Assessment

→ Origin Readiness

→ Value Origin Conditions Record → VODM — Value Origin Documentation Module

The first three modules establish:

Where can value originate?

What about that source can contribute to value?

How is that basis related to the governed value?

VOCM asks:

What must be true for that relationship to become capable of producing or enabling value?

Operational Space

VOCM governs conditions affecting the activation and operation of a Value Origin Relationship.

These conditions may include:

availability; accessibility; capability readiness; resource availability; demand; timing; environmental conditions; operational readiness; technological compatibility; infrastructure availability; complementary capability; economic feasibility; utilization; coordination; scale; knowledge; human capability; network participation; system compatibility; temporal alignment; dependency satisfaction; threshold achievement.

The relevant conditions depend upon the governed value.

VOCM does not prescribe one universal set of conditions.

Origin Relationship ≠ Origin Condition

VORM establishes:

how a source may contribute to value.

VOCM establishes:

what must be true for that relationship to become operationally capable of contributing to value.

Example:

Solar Installation

Value Source:

solar generation system

Value Source Basis:

electricity-generation capability

Value Origin Relationship:

generation capability → production of usable electricity → potential energy value

Value Origin Conditions may include:

sufficient solar irradiation

operational equipment grid or storage connection ability to use or transfer generated electricity.

The relationship can exist while one or more required conditions are absent.

Therefore:

Existing Value Origin Relationship $\neq$ Satisfied Value Origin Conditions

Necessary Conditions

A Necessary Origin Condition is a condition without which the relevant Value Origin Relationship cannot operate for the governed value.

Example:

A manufacturing machine may possess productive capability.

But if production requires electrical power:

electricity availability

may be a necessary condition.

If the condition is absent:

the source remains

and

the capability remains

but the pathway toward value emergence may be inactive.

VOCM therefore prevents the existence of productive capability from being mistaken for realized value.

Enabling Conditions

An Enabling Origin Condition allows or facilitates the Value Origin Relationship without necessarily being the fundamental source of the value.

Examples may include:

infrastructure access; network connectivity; compatible software; transportation; regulatory access where relevant to operation; distribution capability;

specialized equipment; trained personnel.

VOCM governs the condition's role in the value-origin pathway.

It does not govern the external system responsible for establishing that condition.

Conditional Thresholds

Some Value Origin Relationships become materially capable of producing value only after a threshold is reached.

Examples include:

minimum production volume

minimum network participation

minimum utilization

minimum performance

minimum data availability

minimum demand

minimum energy availability

minimum reliability

VOCM may therefore establish:

Condition Variable → Required Threshold → Condition Satisfaction State

A source may be technically capable of creating value while remaining below the threshold required for meaningful value emergence.

Combined Conditions

Value origin frequently depends upon several conditions being satisfied together.

For example:

Technology Capability

Required Infrastructure Qualified Personnel Operational Demand Resource Availability

may collectively create the conditions under which a Value Origin Relationship can operate.

VOCM therefore supports:

Condition Set → Combined Origin Readiness

rather than assuming that each condition independently produces value.

Alternative Condition Paths

The same Value Origin Relationship may operate through different sets of conditions.

For example, a digital service may reach customers through:

Direct Digital Distribution

or

Partner Distribution

or

Integrated Platform Distribution.

Different condition sets may therefore activate alternative pathways toward the same governed value.

VOCM may represent:

Condition Set A → Origin Pathway

or

Condition Set B → Alternative Origin Pathway

This allows value-origin governance to remain adaptable without redefining the underlying value each time implementation changes.

Dependency Conditions

Some conditions depend upon other conditions.

Example:

A production facility may require:

raw materials

but raw-material availability may depend upon:

supplier capability → logistics availability → transport infrastructure → delivery timing.

VOCM may therefore map:

Primary Condition

→ Supporting Condition

→ Dependent Condition

→ Origin Readiness

This is particularly important in complex supply chains, financial systems, infrastructure, digital platforms, and multi-actor ecosystems.

Temporal Conditions

Value Origin Conditions may exist only during particular periods.

They may be:

Continuous

Temporary

Periodic

Seasonal

Event-Triggered

Time-Limited

Delayed

Recurring

For example:

A hydroelectric asset may possess the same physical generation capability throughout the year while water availability changes materially.

The Value Source remains.

The Value Source Basis remains.

The Value Origin Relationship remains.

But the conditions supporting actual value emergence may change over time.

External Conditions

Value origin may depend upon conditions outside the Value Source itself.

Examples include:

customer demand; network availability; weather; energy supply; access to infrastructure; complementary services; resource availability; market access; interoperability; physical environment.

VOCM may recognize these conditions without claiming governance authority over the external domain.

The principle is:

VFM® governs the condition insofar as it affects the value-origin pathway — not the external system that produces the condition.

Internal Conditions

Some conditions arise within the Value Source or Value Object.

Examples include:

operational readiness; functional capability; sufficient capacity; configuration state; resource level; availability; performance threshold.

VOCM may therefore distinguish:

Internal Origin Conditions

from

External Origin Conditions.

Both may be required for the same value-origin pathway.

Demand as a Value Origin Condition

Certain forms of value may depend materially upon demand or beneficiary need.

A capability can exist without producing the relevant value if no beneficiary needs, uses, or can access it within the defined Value Context.

For example:

A transportation service may possess:

vehicles + drivers + routes + operational capability

but passenger-service value may remain unrealized if there is no relevant demand.

VOCM therefore permits demand to function as an Origin Condition where appropriate.

It does not establish market price or economic valuation.

Access as a Value Origin Condition

Value may exist potentially while access prevents its emergence for a specific beneficiary.

Examples:

Medical capability without patient access

Digital capability without network access

Energy capability without transmission access

Knowledge without usable access

Financial infrastructure without participant access

VOCM may therefore govern:

Access Condition Satisfied / Unsatisfied

where access materially determines whether the Value Origin Relationship can operate.

Utilization Condition

Some Value Sources create value only when their capability is used.

For example:

A factory may possess unused production capacity.

The productive capability exists.

Its relationship to production value exists.

The required infrastructure may exist.

But without utilization, the corresponding production value may not emerge.

VOCM can therefore distinguish:

Available Capability

from

Activated Capability.

Complementary Capability Condition

Value may require another capability.

For example:

AI model

may possess analytical capability.

But operational value may require:

usable data + computing infrastructure + integration + decision process.

The AI model alone does not establish the complete value-origin condition set.

VOCM therefore makes complementary capability requirements explicit.

Origin Readiness

VOCM may establish a governed Value Origin Readiness State.

A minimum state model may include:

1. Undefined

The relevant Origin Conditions have not been sufficiently identified.

2. Unsatisfied

One or more necessary Origin Conditions are absent.

3. Partially Satisfied

Some required conditions exist, but the complete condition set is not established.

4. Conditionally Ready

The value-origin pathway can operate only under explicitly defined conditions.

5. Ready

The identified material Origin Conditions necessary for the governed pathway are currently satisfied.

6. Interrupted

Conditions previously supporting the pathway have materially ceased or become unavailable.

These are governance states.

They do not themselves establish Value Emergence.

Origin Readiness ≠ Value Emergence

This distinction is essential to VFM®.

A value-origin pathway may be fully ready without value having emerged yet.

For example:

A manufacturing line may be:

installed

powered

staffed

supplied

tested

ready for operation

while no product has yet been produced.

Therefore:

Origin Readiness = conditions for value emergence are present.

It does not mean:

Value has emerged.

That distinction preserves the boundary between:

Value Origin

and the subsequent:

Value Emergence

governance space.

Condition Failure

An Origin Condition may fail after previously being satisfied.

Examples:

electricity interruption; supply disruption; loss of access; infrastructure failure; disappearance of demand; unavailable personnel; incompatible system update; resource depletion.

VOCM requires material condition failure to remain identifiable.

A condition failure may:

prevent value emergence

or

interrupt the origin pathway

without necessarily destroying the Value Source itself.

Condition Restoration

A failed Origin Condition may later be restored.

Example:

Network outage

→ access condition fails → value-origin pathway interrupted → network restored → access condition satisfied again.

This does not necessarily constitute ReMonet™.

ReMonet™ belongs to later value-restoration governance where value itself has been lost, degraded, dormant, or reduced to a zero-value state as defined by the architecture.

VOCM governs restoration of the origin condition, not restoration of the value state itself.

Condition Change

Origin Conditions may change even when the source and relationship remain stable.

A condition may become:

Satisfied → Partially Satisfied

Satisfied → Unsatisfied

Unsatisfied → Satisfied

Ready → Interrupted

Conditional → Ready

VOCM therefore supports ongoing condition-state updates where Value Origin is monitored over time.

Condition Criticality

Not every Origin Condition has equal importance.

Organizations may classify conditions as:

Critical

Necessary

Enabling

Supporting

Optional

Alternative

The classification should reflect the specific governed value pathway.

A condition classified as critical should have a documented reason for that status.

Condition Dependency Map

For complex systems, VOCM may produce a Value Origin Condition Dependency Map.

Example:

Governed Value

↑

Value Origin Relationship

↑

Condition Set

✓ Energy Availability ✓ Material Availability ✓ Operational Capability ✓ Demand ✓ Distribution Access

Each condition may itself contain dependencies.

This enables organizations to see not only where value can originate, but also what the origin of that value depends upon.

Condition Evidence

Where materially relevant, a claimed Origin Condition should be supportable.

Support may include:

operational data; contractual availability; technical status; resource records; utilization data; demand indicators; system measurements; capacity information; infrastructure status; observed conditions; documented readiness.

VOCM does not own general validation or audit.

Where required:

VALIDOS® may govern validation.

ADIT® may govern audit and evidence.

INTEGROS® may govern integrity.

VOCM governs the value-origin condition being asserted.

Minimum Implementation Framework

A practical VOCM implementation should establish:

1. Value Origin Relationship Input

Receive the governed Value Origin Relationship from VORM.

2. Condition Identification

Identify the conditions materially affecting operation of the value-origin pathway.

3. Condition Classification

Determine whether each condition is necessary, enabling, supporting, critical, optional, or alternative.

4. Condition Dependency

Identify material dependencies between conditions.

5. Condition Threshold

Define relevant thresholds where the condition is not purely binary.

6. Condition State

Determine whether each condition is satisfied, partially satisfied, unsatisfied, conditional, or interrupted.

7. Temporal Applicability

Identify whether the condition is continuous, temporary, periodic, event-triggered, or time-bounded.

8. Origin Readiness

Determine the current readiness of the Value Origin pathway.

9. Condition Support

Identify the basis supporting material condition assertions where required.

10. Value Origin Conditions Record

Create the governed conditions record for downstream documentation and later Value Emergence governance.

Governance Outputs

VOCM may produce:

Value Origin Condition Record Value Origin Condition Set Necessary Origin Condition Record Enabling Origin Condition Record Critical Origin Condition Record Alternative Origin Condition Path Value Origin Condition Dependency Map Value Origin Condition Threshold Value Origin Condition State Value Origin Readiness State Value Origin Condition Failure Record Value Origin Condition Change Record Value Origin Condition Restoration Record Value Origin Conditions Assessment

These outputs provide the governed basis for:

VODM — Value Origin Documentation Module

and subsequently for the transition from:

Value Origin → Value Emergence.

Use Case 1 — Banking: AI Fraud Prevention

Value

A bank has an AI fraud-detection system.

The preceding modules establish:

Value Source: fraud-detection system

Value Source Basis: analytical and transaction-pattern detection capability

Value Origin Relationship: earlier detection of suspicious transactions may prevent or reduce financial loss.

VOCM then identifies the conditions required for that pathway to operate:

relevant transaction data available

system operational fraud patterns detectable within the available information analysis completed before irreversible settlement or loss alerts reach the appropriate decision process intervention capability exists.

This exposes an important distinction.

A bank may own an advanced AI system worth millions of francs.

The technology may function correctly.

But if alerts arrive after transactions become irreversible, one critical Origin Condition fails.

The technical asset still exists.

The analytical capability still exists.

The Value Origin Relationship still exists.

But the expected avoided-loss value may fail to emerge.

VOCM therefore allows the bank to identify exactly which conditions separate:

expensive capability

from

capability capable of originating economic value.

Use Case 2 — Space Mission: Reusable Launch

System

A space organization develops a reusable launch system to reduce lifecycle mission costs.

The preceding modules identify:

Value Sources: reusable vehicle, propulsion system, inspection capability, refurbishment capability, operational learning.

Value Source Bases: reuse, inspection, recovery, refurbishment, repeated operational capability.

Value Origin Relationships: reduced replacement requirements, shorter turnaround, repeated component utilization, and accumulated operational learning may contribute to lower lifecycle mission resource requirements.

VOCM then establishes the conditions necessary for those relationships to operate:

successful recovery

acceptable post-flight component condition inspection capability refurbishment within economically meaningful limits
sufficient reliability across repeated use available launch demand turnaround compatible with mission schedules reuse
cost below relevant replacement alternatives.

The reusable vehicle itself therefore does not automatically create cost value.

If recovery succeeds but refurbishment becomes more expensive than replacement, an important condition fails.

If refurbishment is efficient but launch frequency is too low, another condition may remain unsatisfied.

If both become favorable, the value-origin pathway may become ready.

VOCM therefore transforms:

“Reusable systems create value.”

into the governable question:

“Under which conditions does reusability actually become capable of originating value?”

Foundational Principles

A Value Origin Relationship does not automatically create value.

Value Origin Conditions determine whether the relationship is capable of operating.

Value Source existence does not establish Origin Readiness.

Capability availability does not establish capability utilization.

Necessary conditions must be distinguished from enabling and supporting conditions.

Multiple conditions may jointly determine one value-origin pathway.

External conditions may affect value origin without becoming governed external domains of VFM®.

Origin Conditions may change while the Value Source remains unchanged.

Restoration of an Origin Condition is not automatically restoration of value.

Origin Readiness is not Value Emergence.

Value should not be treated as having emerged merely because the conditions for its emergence exist.

Canonical Closing Statement

Value Origin Conditions Module establishes the conditional layer of Value Origin governance by identifying, classifying, relating, and assessing the conditions required for an established Value Origin Relationship to become capable of producing or enabling the governed value. Through governance of necessary, enabling, supporting, critical, alternative, dependent, temporal, internal, external, threshold-based, and combined conditions, VOCM separates the existence of a Value Source and its capability from the operational conditions required for that capability to contribute to value. By establishing explicit Value Origin Readiness states while preserving the distinction between readiness and actual Value Emergence, VOCM prevents potential value,

available capability, operational readiness, and realized value from being treated as equivalent. The Module therefore creates the final conditional structure required before Value Origin can be documented and the architecture can proceed toward governance of the moment at which value actually comes into existence.
