

Value State Record Module (VSRM)

Value State Record Module (VSRM)

Architecture Ecosystem: Structured Reality Standards™
Architecture Family: VFM® — Value Flow Mechanisms Architecture
Parent Standard: Value State Standard (VSS)
Module: VSRM — Value State Record Module
Operational Layer: Value State Record Layer
Category: Governance & Enforcement
Subcategory: Value Lifecycle Governance
Type: Core Module
Governed Space: Value State Record
Origin ID: VFM-VSS-VSRM-005.5
Version: 1.0
Status: Canonical · Open Standard
Effective Date: 25 August 2026
Compatibility: OOF® Methodology OS™ · GOA™ · ORA™ · VALIDOS® · INTEGROS® · ADIT® · AGA™ · OBIDENTITY®
AI-Readable: Yes
Authority: OOF®
Protection: MIP® — Methodology Intellectual Property Protection
Canonical Language: UCL — Universal Canonical Language

Canonical Definition

Value State Record Module (VSRM) is the fifth Core Module of the Value State Standard (VSS) within VFM® — Value Flow Mechanisms Architecture.

VSRM governs the creation, structuring, preservation, linkage, updating, and lifecycle continuity of the governed Value State Record representing the current determined state of value and the material basis upon which that state was established.

The Module transforms:

Determined Value State + Transition Readiness

→ Governed Value State Record

VSRM ensures that the result of Value State governance does not remain an isolated determination, temporary analytical conclusion, undocumented classification, or context-free label.

It establishes a persistent and reconstructable representation of:

what value state was determined

for what governed value

in what context

for which beneficiary

at what reference point

on what basis

with what limitations

with what transition-readiness status.

Its foundational distinction is:

Value State $\neq$ Value State Record

The state describes the governed condition of value.

The record preserves the governed representation of that condition.

Architectural Position

VSRM is the fifth and final module within VSS.

It follows:

VSIM — Value State Identification Module

→ VSCM — Value State Classification Module

→ VSDM — Value State Determination Module

→ VSTM — Value State Transition Readiness Module

and completes the internal VSS sequence through:

VSRM — Value State Record Module

The internal logic is:

Identify State

→ Classify State

→ Determine State

→ Assess Transition Readiness

→ Record State

VSRM therefore creates the governed output through which the current Value State can remain available to subsequent VFM® processes.

VFM® Governance Flow Position

VSRM completes the fifth governed space within the VFM® governance flow:

Value Context

→ Value Origin

→ Value Emergence

→ Value Recognition

→ Value State

→ Value Change

The VSRM output forms the reference basis against which subsequent material Value Change can be identified.

The architectural bridge is:

Governed Value State Record

→ Observed New Condition

→ Potential Difference

→ Value Change Governance

This is essential because change cannot be meaningfully established without a governed reference state against which the new condition can be compared.

Internal Module Flow

Value State Identification

→ Value State Classification

→ Value State Determination

→ Transition Readiness Assessment

→ Record Object Creation

→ Context Linkage

→ Determination Basis Linkage

→ Reference Point Assignment

→ Limitation & Uncertainty Preservation

→ Transition Readiness Linkage

→ Record Status Assignment

→ Governed Value State Record

→ VCS — Value Change Standard

Operational Space

VSRM governs the methodological space between:

a completed Value State determination

and

a persistent governed representation capable of supporting subsequent value governance.

Its operational space includes:

Value State record identity; governed-value linkage; value-bearing object linkage; beneficiary linkage; context linkage; reference framework linkage; determined state; determination status; determination basis; temporal reference point; applicability; uncertainty; limitations; transition readiness; transition conditions; record version; record status; supersession; historical continuity; state lineage; downstream VFM® availability.

Value State Record Object

Every VSRM process should create an identifiable Value State Record Object.

The Record Object should establish, where applicable:

Record ID
Governed Value ID
Value-Bearing Object
Beneficiary
Value Context
Reference Framework

Reference Point

Value State Classification
Value State Determination

Determination Status

Determination Basis

Uncertainty
Limitations
Transition Readiness State
Applicable Transition Conditions
Record Version
Record Status

This creates a machine-readable and human-interpretable representation of the governed Value State.

Record Context Principle

A Value State Record must not detach the state from the context that gives it meaning.

A record containing only:

Asset X — Zero Value

is methodologically insufficient where the actual determination was:

Asset X — Zero Value for Beneficiary B within Operational Context C at Reference Point T.

The difference is fundamental.

Without context preservation, a valid narrow determination may later be interpreted as a universal statement about the object.

VSRM therefore requires:

State + Context + Reference Point

to remain linked.

Record Identity

Every material Value State Record should be uniquely identifiable.

Record identity allows organizations to distinguish:

current records; historical records; superseded records; corrected records; parallel context-specific records; beneficiary-specific records; provisional records; conditional records.

Record identity is not the same as identity of the underlying asset or object.

Therefore:

Value State Record Identity $\neq$ Asset Identity

OBIDENTITY® or another applicable identity architecture may govern the underlying object identity.

VSRM governs the identity of the Value State Record itself.

Reference Point

Every Value State Record must preserve the temporal or event-based point to which the determination applies.

This may be:

timestamp; date; reporting period; transaction point; operational event; assessment point; lifecycle milestone; defined condition.

Without a reference point, the organization may later confuse:

what was true then

with

what is true now.

This becomes particularly important where value changes rapidly.

State Record $\neq$ Permanent Truth

A Value State Record represents the governed determination applicable at its reference point.

It does not establish permanent value reality.

A record may legitimately state:

Active Value — 25 August 2026

while a later record states:

Degraded Value — 14 October 2026

and another later record states:

ZVA™ — 9 January 2027.

These records do not invalidate one another where each accurately represents its applicable governed reference state.

Together they create:

Value State History.

Current Record and Historical Record

VSRM distinguishes between:

Current Value State Record

and

Historical Value State Record.

When a new Value State is legitimately determined, the previous record should normally remain preserved as historical state information rather than being overwritten as though the earlier determination never existed.

The logic is:

Current Record

→ Material Change

→ New Determination

→ New Current Record

while:

Previous Current Record

→ Historical Record

This creates state continuity.

Record Versioning

A Value State Record may require versioning where:

information is corrected; uncertainty is updated; limitations change; supporting information changes; determination status changes; transition readiness changes; contextual information is refined.

Versioning must distinguish:

Record Revision

from

Value State Change.

Correcting a spelling error does not mean value changed.

Adding missing documentation does not necessarily mean value changed.

Updating transition readiness may not mean the underlying Value State changed.

Therefore:

Record Change $\neq$ Value Change

Record Supersession

Where a new governed Value State replaces the previous current state, VSRM should preserve the supersession relationship.

Example:

VSR-000145 / Active Value

→ superseded by →

VSR-000186 / Degraded Value

→ superseded by →

VSR-000241 / ZVA™

The chain creates a reconstructable value-state lifecycle.

The previous record should not disappear merely because it is no longer current.

Parallel Value State Records

One value-bearing object may legitimately have multiple simultaneous Value State Records.

For example:

Industrial Facility

may have:

Active Value — Production Context

Strategic Value — Emergency Capacity Context

Degraded Value — Energy Efficiency Context

Conditional Value — Redevelopment Context

These records are not necessarily contradictory.

They represent distinct governed value relationships.

VSRM must therefore support:

One Object → Multiple Context-Bound Value State Records

Beneficiary-Specific Records

The same value-bearing object may carry different Value States for different beneficiaries.

For example:

Legacy Industrial Equipment

may represent:

ZVA™ — Company A / Current Production Context

while simultaneously representing:

Active Value — Company B / Secondary Production Context.

VSRM must preserve these beneficiary distinctions.

Otherwise, a zero-value determination for one beneficiary could incorrectly erase value existing for another.

Value Asset™ Record

Where VSDM determines a governed state corresponding to:

Value Asset™

VSRM preserves that determination as an explicit Value State Record.

The record should preserve:

why the governed value qualifies as existing positive value

and

the context within which that determination applies.

A Value Asset™ Record does not automatically establish:

legal title; accounting asset recognition; market price; tax status; regulatory classification; transfer rights.

It records the VFM® Value State.

ZVA™ — Zero Value Asset™ Record

Where a governed value has legitimately reached:

ZVA™ — Zero Value Asset™

VSRM creates a persistent record of that zero-value determination.

The record must preserve:

what value reached zero

for which beneficiary

within which context

at what reference point

on what determination basis

subject to what limitations

with what recovery or transition conditions where applicable.

This prevents:

ZVA™

from becoming an unexplained universal label attached permanently to an object.

A later state may legitimately move away from ZVA™ where new value emerges, is recognized, and a new state is determined.

Unknown-State Record

Where VSDM determines that available information is insufficient to establish the current Value State, VSRM may preserve:

Indeterminate Value State

rather than forcing a positive or zero-value record.

This protects the architecture from converting:

missing information

into

false value certainty.

Conditional-State Record

A conditional determination must preserve its conditions.

Example:

Conditional Value

may depend upon:

License Renewal

Critical Supplier Availability

Network Access

Regulatory Approval

Energy Availability

Restoration Completion

If those conditions disappear from the record, downstream systems may incorrectly treat conditional value as unconditional value.

VSRM therefore treats conditions as part of the governed record.

Uncertainty Preservation

Material uncertainty affecting the Value State must remain connected to the record.

Relevant uncertainty may concern:

capability; utilization; recoverability; beneficiary relevance; market relevance; technical condition; dependency availability; strategic significance; temporal applicability; data completeness.

VSRM does not eliminate uncertainty.

It ensures that downstream use cannot silently forget it.

Limitation Preservation

A Value State determination may contain explicit limitations.

For example:

ZVA™ applies only to the current manufacturing context and does not assess component resale value.

That limitation must remain part of the record.

Without it, a valid context-specific state can become an invalid universal conclusion.

Therefore:

State Record without Material Limitations = Incomplete Governance Record

where those limitations affect legitimate interpretation.

Transition Readiness Record

VSRM preserves the transition-readiness result produced through VSTM.

The record may therefore contain:

Current Value State: Active Value

Transition Readiness: Transition-Sensitive

or:

Current Value State: ZVA™

Transition Readiness: Recovery-Ready

This creates a richer state representation than a static value label.

It allows downstream systems to know both:

where value is now

and

whether that state is becoming unstable or ready to change.

State Lineage

VSRM enables the construction of a Value State Lineage.

Example:

Potential Value

→ Value Emergence

→ Recognized Value

→ Active Value

→ Degraded Value

→ ZVA™

→ Recoverable Value

→ Active Value

The record lineage does not itself govern all these transitions.

It preserves the sequence of governed states and their relationships as they pass through VFM®.

This creates the informational foundation required to reconstruct the value lifecycle.

Record Continuity

Value governance becomes substantially stronger when state records remain continuous across time.

A continuous record can answer:

What was the value state before the event?

What changed?

When did it change?

What state followed?

Was the previous state already transition-sensitive?

Was zero value temporary or persistent?

Was value later recovered?

This is essential for downstream Value Change governance.

Record Integrity Boundary

VSRM defines what must be represented within the Value State Record.

It does not replace general information-integrity governance.

Where record integrity, tamper resistance, provenance assurance, authenticity, or broader integrity controls are required, the relevant integrity architecture may govern those properties.

The boundary is:

VSRM governs what the Value State Record must represent.

INTEGROS® may govern whether that record remains trustworthy and intact.

Auditability Boundary

VSRM creates a reconstructable Value State Record.

It does not itself conduct an audit.

ADIT® may subsequently examine:

whether the record existed; whether supporting information is preserved; whether changes are traceable; whether determinations can be reconstructed; whether state history was altered; whether records correspond to observed evidence.

Therefore:

Value State Recording ≠ Audit

Accounting Boundary

A Value State Record is not an accounting ledger entry.

The same physical or digital object may have:

accounting carrying value

and

VFM® governed Value State

simultaneously.

These may differ legitimately because they answer different questions.

VSRM must not redefine accounting treatment.

However, accounting systems may consume VFM® state information where an organization or future methodology chooses to use it as a governed analytical input.

Tax Boundary

A Value State Record does not itself create:

taxable income; tax liability; deductible loss; depreciation; taxable asset value; tax recognition.

A future tax architecture could use VFM® Value State Records as governed inputs into a separate tax determination mechanism.

The architectural separation remains:

VFM® records the governed state of value.

The tax architecture determines the tax consequence.

Blockchain and Distributed Ledger Compatibility

VSRM can be implemented using conventional databases, enterprise systems, distributed ledgers, blockchain systems, digital asset infrastructures, or future record technologies.

A blockchain may preserve:

record timestamp; record identity; state version; supersession; provenance reference; state-transition reference.

But:

Blockchain Record ≠ Governed Value State

The technology may preserve the record.

VFM® defines the methodological meaning of what the record represents.

This distinction allows VSRM to remain technology-neutral.

AI and Machine-Readable Value State Records

VSRM is designed to support machine-readable implementation.

An AI or automated system may consume structured fields such as:

Value ID

Object ID

Beneficiary ID

Context ID

Reference Point

Value State

Determination Status

Transition Readiness

Uncertainty

Limitations

Record Version

This allows Value State governance to become part of automated:
asset management; banking; insurance; industrial systems; public finance; digital infrastructure; AI resource allocation; investment systems; operational optimization.

Machine readability must not remove contextual meaning.

Minimum Implementation Framework

A minimum VSRM implementation should establish:

1. Record Identity

Create a unique Value State Record identifier.

2. Governed Value Link

Identify the governed value represented by the record.

3. Context Link

Preserve the value-bearing object, beneficiary, context, and applicable reference framework.

4. State Determination

Record the determined Value State and determination status.

5. Determination Basis

Preserve or link the material basis supporting the state.

6. Reference Point

Record the time, period, event, or other reference point to which the state applies.

7. Uncertainty and Limitations

Preserve material uncertainty, conditions, and limitations.

8. Transition Readiness

Preserve the applicable VSTM readiness state and material transition conditions.

9. Version and Status

Identify whether the record is current, historical, provisional, conditional, suspended, superseded, or otherwise governed.

10. Continuity Link

Link the record to prior and subsequent Value State Records where applicable.

Governance Outputs

VSRM may produce:

Value State Record Current Value State Record Historical Value State Record Value State Record ID Value State Context Record Value State Determination Link Value State Reference Point Value State Uncertainty Record Value State Limitation Record Value State Transition Readiness Record Value State Version Record Value State Supersession Record Value State History Value State Lineage

Value Asset™ Record

ZVA™ — Zero Value Asset™ Record

These outputs complete the governed output of the Value State Standard (VSS) and establish the reference basis for Value Change Standard (VCS).

Use Case 1 — Banking and Collateral: From

Static Asset Register to Governed Value-State

History

A bank holds thousands of loans secured against:

industrial machinery; commercial property; infrastructure; vehicles; equipment; intellectual property; digital assets; production capacity.

A traditional system may preserve:

Asset ID

Borrower

Original valuation

Current accounting amount

Collateral category.

But the bank may lack a structured record of how the actual governed value condition evolved over time.

VSRM allows the bank to preserve:

Value State Record 1

→ Active Value

→ production capability strong

→ transition readiness stable

then:

Value State Record 2

→ Degraded Value

→ utilization falling

→ maintenance burden increasing

→ transition-sensitive

then:

Value State Record 3

→ ZVA™ within Primary Production Context

→ capability no longer economically usable for that beneficiary

while preserving:

Secondary Resale Context → Recoverable Value.

The bank no longer sees only:

“Collateral exists.”

It sees:

how the governed value attached to that collateral evolved.

This can support stronger:

credit monitoring

collateral governance

risk detection

restructuring analysis

capital allocation

and

recovery planning.

The critical advantage is historical reconstructability.

When a major loss occurs, the institution can examine not merely the final state, but the complete governed state path that preceded it.

Use Case 2 — Blockchain and Digital Assets:

Recording Value State Without Confusing

Ownership, Price, and Value

A digital infrastructure may contain millions of tokens, digital rights, licenses, data assets, computational resources, digital objects, or blockchain-linked assets.

A blockchain can prove that:

an object exists

a transaction occurred

ownership changed

or

a record was timestamped.

But those facts do not necessarily establish:

what governed Value State the asset currently occupies.

VSRM can create a separate machine-readable Value State layer.

For example:

Digital Asset A

→ **Active Value**

- beneficiary: Network X
- context: operational utility
- reference point: T1

Later:

Digital Asset A

→ **Dormant Value**

- utility temporarily inactive

Later:

Digital Asset A

- ZVA™

- zero operational value within Network X

while simultaneously:

Digital Asset A

→ **Recoverable Value**

- secondary interoperability context.

The blockchain may preserve the records and their chronology.

VFM® defines what those records mean.

This separation prevents:

token price

ownership

transaction history

and

governed value state

from being treated as the same concept.

It also creates the possibility of portable Value State Records that can be consumed by financial systems, asset-management systems, insurance systems, AI agents, marketplaces, or future value infrastructures without losing their original context.

Foundational Principles

Value State is not Value State Record.

A Value State Record must preserve the context that gives the state meaning.

A Value State Record represents a governed reference point, not permanent truth.

Historical states must not disappear merely because a new current state exists.

Record revision is not automatically Value Change.

One object may carry multiple legitimate context-specific Value State Records.

One object may carry different Value States for different beneficiaries.

ZVA™ in one context does not establish universal zero value.

Unknown value must remain distinguishable from zero value.

Conditional value must preserve its conditions.

Material uncertainty and limitations must travel with the Value State Record.

Transition readiness should remain visible alongside the current Value State.

Blockchain may preserve a Value State Record; it does not determine the Value State.

Accounting value, market price, ownership, tax treatment, and VFM® Value State remain distinct concepts.

A governed history of value requires states to remain reconstructable across time.

Canonical Closing Statement

Value State Record Module completes the Value State Standard by transforming identified, classified, determined, and transition-readiness-assessed value conditions into persistent, context-bound, beneficiary-aware, reference-point-specific, uncertainty-preserving, limitation-aware, versioned, and historically reconstructable Value State Records. Through governance of record identity, state representation, context linkage, determination basis, temporal applicability, conditions, uncertainty, transition readiness, versioning, supersession, parallel states, historical continuity, Value Asset™ records, and ZVA™ — Zero Value Asset™ records, VSRM prevents current value conditions from becoming detached from the circumstances that give them meaning or from overwriting the value history that preceded them. By separating Value State recording from object identity, accounting, taxation, blockchain technology, audit, integrity, and Value Change itself, VSRM creates the persistent reference layer required for VFM® to compare what value was with what value subsequently becomes. A value lifecycle becomes governable only when its states can remain identifiable, contextualized, connected, and reconstructable across time.
