Canonical Definition

Value Extinction Standard (VXSS) is the Parent Standard within VFM® — Value Flow Mechanisms Architecture that governs the terminal lifecycle condition in which previously existing value ceases to exist as recoverable value within the governed lifecycle.

VXSS establishes the methodological boundary between zero value and extinguished value by determining when a value condition has moved beyond degradation, dormancy, impairment, loss, nullification, or recoverable zero value into a state in which restoration of the relevant value is no longer legitimately available within the same governed lifecycle.

The Standard does not define every physical, economic, technological, legal, organizational, market, environmental, or operational event capable of causing extinction.

Its task is narrower:

to determine when the value consequence of those events has crossed the governed boundary from recoverable value into terminal value finality.

Core Question

When does value cease to exist as recoverable value within the governed lifecycle?

Architectural Position

VXSS occupies the eleventh and final governed space of the VFM® value lifecycle.

It follows:

Value Restoration Standard (VRSS).

The preceding standards govern value as it:

emerges

→ is identified

→ is attributed

→ enters a governed state

→ changes

→ develops

→ degrades

→ reaches zero where applicable

→ may be restored where recoverability remains.

VXSS governs the final question:

When is restoration no longer a legitimate continuation of the same value lifecycle?

This makes Value Extinction the terminal lifecycle boundary of VFM®.

Governance Flow Position

Existing Value → Value Development / Value Change → Value Degradation → Value Nullification where applicable → ZVA™ — Zero Value Asset™ where applicable → Restoration Potential Assessment → Value Extinction Conditions → Value Extinction Threshold → Value Extinction Determination → Value Finality → Value Extinction Record

The critical architectural boundary is:

Zero Value ≠ Value Extinction.

Operational Space

VXSS governs the space between:

value that remains recoverable

and

value that has ceased to exist as recoverable value within the governed lifecycle.

Its operational space includes:

extinction-condition identification; recoverability assessment; restoration-potential exhaustion; extinction-threshold definition; threshold satisfaction; irreversible value loss; lifecycle termination; value identity discontinuity; terminal impairment; terminal obsolescence; terminal loss of utility; terminal loss of capability; terminal loss of relevance; terminal loss of rights where value-dependent; terminal loss of recoverable economic function; extinction determination; value finality; terminal-state recording; distinction between extinction and temporary zero value; distinction between extinction and dormancy; distinction between extinction and degradation; distinction between extinction and new Value Emergence.

Operational Scope

VXSS may apply to value associated with:

physical assets; industrial assets; infrastructure; digital assets; data; intellectual property; technologies; products; services; productive capabilities; operational capabilities; contractual or economic rights; organizational capabilities; financial or economic assets; information; knowledge structures; platforms; systems; market relationships; other governable Value Objects.

Value Extinction does not require destruction of the underlying object.

An object may continue to exist while a particular value associated with it becomes extinct.

Value Object ≠ Value

VXSS preserves a fundamental distinction:

Object Existence ≠ Value Existence.

A machine may physically remain after its productive value becomes extinct.

A dataset may remain stored after its relevant informational value becomes extinct.

A technology may remain technically functional after its commercial value becomes extinct.

An intellectual property right may remain legally registered after a particular economic value becomes extinct.

The continued existence of the object therefore does not prove continued recoverability of the governed value.

Zero Value ≠ Value Extinction

This is the foundational distinction of VXSS.

A value may reach:

zero

without becoming extinct.

A ZVA™ — Zero Value Asset™ may retain:

restoration potential; dormant utility; technological recoverability; economic recoverability; informational recoverability; functional recoverability; strategic recoverability; rights-based recoverability; future relevance.

Therefore:

Zero Value may be a state.

Value Extinction is a terminal lifecycle determination.

ZVA™ and Extinction

A ZVA™ may remain within the active governed lifecycle because ReMonet™ may still restore previously existing value.

The lifecycle may therefore legitimately contain:

Positive Value

→ DeMonet™

→ ZVA™

→ ReMonet™

→ Restored Value.

VXSS applies when that restoration pathway is no longer legitimately available for the relevant value within the same governed lifecycle.

Therefore:

ZVA™ ≠ Extinguished Value.

Value Extinction Principle

Value Extinction occurs only when sufficient governed conditions establish that the relevant previously existing value no longer remains recoverable within the governed lifecycle.

The determination must relate to a defined value.

It must not be inferred merely because:

current value is zero; an asset is unused; an asset is obsolete; a market temporarily disappeared; restoration is expensive; restoration has not yet been attempted; one restoration attempt failed; current technology cannot restore the value; an organization no longer wants the asset; a business model has temporarily failed.

Extinction requires a stronger governed basis.

Recoverability Principle

Recoverability is the central boundary variable of VXSS.

The relevant question is not merely:

Does the value exist now?

It is:

Does the previously existing value remain legitimately recoverable within the governed lifecycle?

Recoverability may depend upon:

physical possibility; technical possibility; informational continuity; legal continuity; identity continuity; economic viability where materially relevant; functional continuity; restoration mechanism availability; remaining asset capability; preservation of the underlying value basis; temporal conditions; contextual conditions.

Recoverability ≠ Immediate Restorability

A value does not need to be immediately restorable in order to remain recoverable.

Restoration may require:

new technology; capital; time; infrastructure; regulatory change; reconstruction; market recovery; technical intervention; data reconstruction; new operational capability.

Therefore:

Not Currently Restorable ≠ Extinct.

VXSS must avoid premature extinction determinations based solely on current limitations.

Restoration Cost ≠ Extinction

A value may be economically irrational to restore while still technically recoverable.

Conversely, unlimited expenditure does not guarantee that extinct value can be restored.

VXSS therefore separates:

Restoration Economics

from

Value Existence.

High restoration cost may influence organizational decisions.

It does not automatically establish Value Extinction.

Failed Restoration ≠ Extinction

A failed ReMonet™ process does not automatically prove extinction.

Failure may result from:

incorrect restoration method; insufficient resources; incomplete intervention; technical execution failure; incorrect assumptions; missing capabilities; premature intervention; temporary external conditions.

VXSS requires the failure of a particular restoration attempt to remain distinct from the broader determination that the relevant value itself is no longer recoverable.

Therefore:

Failed ReMonet™ ≠ Value Extinction.

Extinction Conditions

VXSS requires explicit conditions capable of supporting an extinction determination.

Depending upon the governed value, conditions may include:

destruction of the underlying value basis; irreversible loss of required information; irreversible loss of identity continuity; permanent loss of necessary rights; irreversible functional destruction; permanent technological incompatibility; irreversible disappearance of the relevant utility; loss of the conditions necessary for restoration; permanent elimination of the relevant economic relationship; irreversible environmental change;

terminal structural deterioration; exhaustion of all legitimate restoration pathways; another defined terminal condition.

No single universal condition applies to every value class.

Extinction Threshold

Value Extinction requires a threshold separating:

recoverable impairment

from

terminal value loss.

The threshold may be:

physical; functional; informational; technological; legal; economic; operational; temporal; contextual; composite.

The threshold must correspond to the governed value relationship.

VXSS does not require one universal numerical extinction threshold.

Threshold Crossing ≠ Automatic Determination

Even where an extinction threshold appears to have been crossed, the lifecycle should not automatically terminate without a governed determination.

The threshold provides the basis for evaluation.

The extinction determination establishes the terminal state.

Therefore:

Threshold Crossing ≠ Extinction Determination.

Extinction Determination

A Value Extinction Determination establishes that:

the relevant previously existing value no longer remains recoverable within the governed lifecycle.

The determination should identify:

the Value Object; the relevant value; prior Value State; applicable extinction conditions; extinction threshold; recoverability basis; restoration pathways considered; material uncertainty;

determination basis; effective extinction point; finality consequences.

Extinction Uncertainty

Value Extinction should not be declared where material uncertainty prevents a legitimate terminal determination.

Where recoverability cannot currently be established or excluded, the appropriate state may remain:

Indeterminate

rather than:

Extinct.

This is especially important for:

emerging technologies; inaccessible data; future reconstruction capability; uncertain rights; unresolved ownership; rapidly changing markets; evolving scientific capability.

VXSS must not transform uncertainty into finality.

Temporary Impossibility ≠ Extinction

A value may temporarily be impossible to restore because of:

unavailable technology; regulatory restriction; inaccessible infrastructure; temporary market conditions; missing resources; geopolitical conditions; temporary legal barriers.

If the underlying value remains recoverable when those conditions change, extinction has not necessarily occurred.

Dormancy ≠ Extinction

Dormant value may remain recoverable even where it has not produced active utility for a long period.

Examples include:

dormant intellectual property; archived data; inactive infrastructure; unused productive capacity; inactive rights; temporarily irrelevant technology.

Time alone does not establish extinction.

Obsolescence ≠ Automatic Extinction

Obsolescence may contribute to Value Degradation or Value Nullification.

It does not automatically establish extinction.

An obsolete technology may:

regain historical value; gain collector value; become strategically relevant; be repurposed; be modernized; regain functionality; support another value relationship.

VXSS therefore requires the specific governed value to be evaluated rather than treating the label obsolete as a terminal determination.

Extinction of One Value ≠ Extinction of All Value

A single Value Object may support multiple value relationships.

For example, an industrial machine may lose:

productive manufacturing value

while retaining:

scrap value

historical value

training value

or

component value.

VXSS may therefore determine extinction of one governed value without declaring the entire object valueless.

This distinction prevents Value Extinction from becoming an object-destruction classification.

Value Identity Continuity

Restoration requires continuity between:

the value that previously existed

and

the value claimed to have returned.

Where that continuity is permanently lost, restoration may no longer be a legitimate description.

This creates an important extinction boundary.

If a later value appears but represents a materially different value relationship, it may constitute:

new Value Emergence

rather than restoration of the extinguished value.

Extinction ≠ New Emergence Prohibition

Value Extinction terminates a particular governed value lifecycle.

It does not mean the Value Object can never possess value again.

A new value may later emerge through:

new technology; new use; new market; new rights; new information; new functionality; new context; new demand; new strategic relevance.

Where the later value does not represent recovery of the extinguished value, it should enter governance as:
new Value Emergence.

Therefore:

Value Extinction ≠ Permanent Prohibition of Future Value.

Value Finality

Once Value Extinction has been legitimately determined, VXSS establishes Value Finality for the relevant value lifecycle.

Value Finality means that the extinguished value is no longer treated as:

degraded value; dormant value; zero value awaiting restoration; a ReMonet™ candidate; pending restored value.

The lifecycle has reached its terminal condition.

Finality ≠ Erasure

Value Finality does not erase the previous value lifecycle.

The governed record should preserve:

Value Emergence

→ Value States

→ Value Changes

→ Value Development

→ Value Degradation

→ Value Nullification where applicable

→ Restoration history where applicable

→ Value Extinction

→ Value Finality.

Extinction ends the lifecycle.

It does not delete it.

Finality Reopening

A legitimate extinction determination should not be casually reversed.

Where new evidence later demonstrates that the extinction determination itself was incorrect, the organization may require:

Determination Review

rather than treating the value as having been restored.

This distinction is important.

If the value was never actually extinct, correcting the record is:

Extinction Determination Correction

not

ReMonet™.

Value Extinction States

VXSS may recognize minimum governance states such as:

1. Extinction Not Established

Available evidence does not establish that the value has ceased to be recoverable.

2. Extinction Indeterminate

Available evidence is insufficient to determine whether recoverability remains.

3. Extinction Threshold Approaching

Material conditions indicate proximity to a defined extinction threshold, but terminal loss has not yet been established.

4. Extinction Threshold Reached

The defined threshold has been reached, requiring formal extinction determination.

5. Value Extinct

The relevant value has been determined to no longer exist as recoverable value within the governed lifecycle.

6. Value Final

The extinction determination has entered final lifecycle status and the value is no longer eligible for restoration governance within that lifecycle.

These are governance states and should be adapted to the relevant implementation context.

VXSS Boundary with Value Degradation

Standard

VDGS governs declining value while value continues to exist.

VXSS governs the terminal condition where recoverable value no longer exists.

Therefore:

Declining Value $\neq$ Extinguished Value.

VXSS Boundary with Value Nullification

Standard

VNS governs the transition from positive value into a zero-value condition.

VXSS governs whether recoverability itself has ended.

Therefore:

Zero Value $\neq$ Value Extinction.

A ZVA™ may remain recoverable.

An extinguished value does not.

VXSS Boundary with Value Restoration Standard

VRSS governs recovery of previously impaired, degraded, dormant, lost, inaccessible, or zero value where restoration remains legitimate.

VXSS establishes the boundary beyond which restoration no longer represents continuation of the same value lifecycle.

Therefore:

Recoverable Value $\rightarrow$ VRSS

Non-Recoverable Value $\rightarrow$ VXSS

VXSS Boundary with Value State Standard

VSS determines the current governed state of value.

VXSS determines terminal lifecycle extinction and finality.

A zero Value State under VSS must not automatically be interpreted as Value Extinction.

VXSS Boundary with Value Change Standard

Value Change governs what materially happened to value.

Value Extinction governs whether the consequence has become terminal.

A material change may contribute to extinction without itself constituting an extinction determination.

VXSS Boundary with Value Emergence

Once a value has legitimately reached Value Finality, later value cannot automatically be classified as restoration.

The architecture must first determine whether the later value represents:

correction of an incorrect extinction determination

or

new Value Emergence.

This protects the semantic integrity of the lifecycle.

Foundational Principles

Zero Value is not Value Extinction.

ZVA™ may retain restoration potential.

Value Extinction requires loss of recoverability, not merely absence of current value.

Object existence does not prove value existence.

Object destruction is not required for Value Extinction.

Not currently restorable does not mean extinct.

Restoration cost does not determine whether value exists.

Failed restoration does not automatically establish extinction.

Dormancy is not extinction.

Obsolescence is not automatically extinction.

Extinction of one value does not extinguish every value associated with the same object.

Threshold crossing is not itself an Extinction Determination.

Uncertainty must not be converted into finality.

Value Finality ends a governed value lifecycle; it does not erase its history.

An extinguished value cannot legitimately enter ReMonet™ within the same governed lifecycle.

Future value may emerge after extinction, but new Value Emergence must remain distinct from restoration of extinguished value.

Canonical Closing Statement

Value Extinction Standard establishes the terminal governance layer of VFM® — Value Flow Mechanisms Architecture by determining when previously existing value ceases to remain recoverable within its governed lifecycle. Through governance of extinction conditions, recoverability, restoration potential, extinction thresholds, terminal uncertainty, extinction determination, Value Finality, value identity continuity, historical preservation, and terminal lifecycle records, VXSS establishes the critical distinction between zero value and extinguished value. The Standard prevents temporary impairment, dormancy, obsolescence, failed restoration, high restoration cost, or a ZVA™ — Zero Value Asset™ from being prematurely interpreted as terminal value loss while also providing a formal point at which a value that can no longer legitimately be recovered ceases to remain within restoration governance. By preserving the distinction between Value Extinction, Value Nullification, Value Restoration, and future Value Emergence, VXSS closes the governed value lifecycle without preventing new value from later emerging from the same underlying object. Value Extinction therefore represents not the

moment when value merely reaches zero, but the moment when the governed lifecycle can no longer legitimately support the proposition that the same value can return.

Mahlad

Value Extinction Standard (VXSS)

Architecture: VFM® — Value Flow Mechanisms Architecture Category: Governance & Enforcement Subcategory: Value Lifecycle Governance Canonical Definition: Value Extinction Standard governs the terminal lifecycle condition in which previously existing value ceases to remain recoverable within the governed lifecycle and establishes the methodological boundary between recoverable zero value and legitimate Value Finality. Governed Space: Value Extinction Value becomes legitimately extinct only when its recoverability as the same governed value has ended within the defined lifecycle; zero value, dormancy, obsolescence, failed restoration, or temporary impossibility do not by themselves establish extinction. → [View Standard](#)
