Governed Space

Assumption Sensitivity

Canonical Definition

Assumption Sensitivity Module (ASNM) defines the governance conditions under which the relationship between change in a Predictive Assumption and change in the governed prediction, predictive conditions, methodology applicability, probability, uncertainty, feasibility, or legitimate interpretation is identified, assessed, bounded, and represented.

ASNM determines how sensitive the prediction is to assumptions on which it depends.

transforms:

Assumption Dependency

into:

Governed Assumption Sensitivity

by establishing how materially different assumption states may affect the predictive structure.

ASNM does not determine final Assumption Materiality and does not govern actual assumption-state change.

Those functions belong to:

AMAM — Assumption Materiality Module

and:

ACGM — Assumption Change Governance Module.

Foundational distinction:

Dependency $\neq$ Sensitivity

A prediction may depend upon an assumption while remaining relatively stable across reasonable changes in that assumption.

Another prediction may change dramatically when the same assumption moves only slightly.

Operational Role

ASNM serves as the third internal governance space of the Prediction Assumption Standard (PAS) .

It receives:

Identified Predictive Assumptions

Governed Assumption Dependency Map

and evaluates how changes in those assumptions may affect the prediction and its governed predictive conditions.

The module asks:

How much, in what direction, and under what conditions can the prediction change when a governed assumption changes, weakens, moves outside its expected range, or fails?

The governed progression is:

Governed Assumptions + Governed Dependency Structure → Sensitivity Identification → Sensitivity Direction → Sensitivity Range → Threshold Assessment → Propagation Assessment → Governed Assumption Sensitivity Profile

The resulting profile becomes input to:

AMAM — Assumption Materiality Module.

Internal Module Flow

Predictive Assumption Identification → Assumption Dependency Mapping → → Assumption Sensitivity → Assumption Materiality → Assumption Change Governance

Current Position: Assumption Sensitivity

Module Operational Space

ASNM governs:

assumption sensitivity identification; prediction sensitivity to assumptions; local sensitivity; global sensitivity; directional sensitivity; non-directional sensitivity; linear sensitivity; nonlinear sensitivity;

threshold sensitivity; discontinuous sensitivity; conditional sensitivity; contextual sensitivity; temporal sensitivity; horizon sensitivity; boundary sensitivity; probability sensitivity;

uncertainty sensitivity; confidence sensitivity; feasibility sensitivity; methodology-applicability sensitivity; interpretation sensitivity; reliance sensitivity; compound sensitivity; dependency-mediated sensitivity; sensitivity propagation; sensitivity concentration; sensitivity interaction; sensitivity asymmetry; sensitivity range; tolerance range; sensitivity threshold; critical threshold; sensitivity uncertainty; sensitivity state; sensitivity change; historical sensitivity; and sensitivity traceability.

Module Function

Not every assumption affects a prediction in the same way.

Consider two assumptions:

Assumption A: Fuel price remains between 1.40 and 1.60.

Assumption B: The only distribution center remains operational.

A small change in fuel price may slightly affect the prediction.

Failure of the distribution center may fundamentally alter it.

Both are assumptions.

Both may be dependencies.

Their sensitivity characteristics are completely different.

ASNM makes that difference governable.

Assumption Sensitivity

Assumption Sensitivity represents the degree and form of change in the prediction or its governed predictive conditions resulting from change in a Predictive Assumption.

Sensitivity may concern changes in:

predicted outcome; probability; uncertainty; confidence; prediction range; feasibility; methodology applicability; interpretation; permitted reliance; prediction state.

Dependency ≠ Sensitivity

ADMM determines whether a dependency exists.

ASNM determines how consequential changes in that dependency may be to the prediction.

For example:

A demand forecast may depend upon temperature.

However, between 18°C and 22°C the forecast may change very little.

Above 30°C, demand may change substantially.

The dependency exists throughout.

The sensitivity changes across the condition range.

Dependency Presence ≠ Constant Sensitivity

Sensitivity Direction

Sensitivity may possess direction.

An assumption change may tend to:

increase predicted outcome; decrease predicted outcome; increase predicted probability; decrease predicted probability; widen uncertainty; narrow uncertainty; increase feasibility; decrease feasibility; change methodology applicability; change interpretation; restrict reliance.

Where directional behavior is known, it should remain identifiable.

Positive Sensitivity

Positive Sensitivity may exist where an increase or strengthening of an assumption condition tends to increase a predictive output.

For example:

Higher available production capacity → Higher predicted production output

where supported by the predictive structure.

Negative Sensitivity

Negative Sensitivity may exist where an increase in an assumption condition tends to reduce a predictive output.

For example:

Higher borrowing cost → Lower predicted investment activity

within the governed context.

Non-Directional Sensitivity

Some assumption changes affect prediction stability without a simple positive or negative direction.

A change may:

widen uncertainty; alter model applicability; move the prediction into a different state; require a different scenario; change permitted reliance.

ASNMM does not force directional representation where the relationship is not meaningfully directional.

Sensitivity Magnitude

Sensitivity Magnitude represents how substantially the governed prediction or relevant predictive condition may change when an assumption changes.

Possible governed states may include:

Minimal

Low

Moderate

High

Extreme

Unable to Determine

The implementation may use quantitative measures where appropriate.

Low Sensitivity

A Low-Sensitivity Assumption may change materially without causing substantial change in the prediction within the relevant range.

Low sensitivity does not automatically mean the assumption is immaterial.

For example, an assumption may have little effect on predicted value but large implications for legitimate reliance.

Low Sensitivity $\neq$ Low Materiality by Default

High Sensitivity

A High-Sensitivity Assumption is one where relatively limited change may cause substantial change in the prediction or predictive conditions.

High sensitivity may justify closer monitoring or stronger disclosure.

It does not by itself determine materiality.

Extreme Sensitivity

Extreme Sensitivity exists where small assumption variation may fundamentally alter:

predicted outcome; probability structure; feasibility; methodology applicability; permitted interpretation.

Such assumptions may become candidates for Critical Assumption classification under AMAM.

Sensitivity Range

Sensitivity must be interpreted within a governed range.

An assumption may be stable within one interval and highly sensitive outside it.

For example:

Interest Rate Assumption: 2%–4%

may produce limited forecast change.

Above 6%, the prediction may materially shift.

Therefore:

Sensitivity at Range A $\neq$ Sensitivity at Range B

Tolerance Range

A Tolerance Range is a bounded interval within which assumption change produces no material or only limited predictive effect.

Example:

Supplier delivery variance ± 2 days

may not materially affect a six-month production forecast.

Outside that range, sensitivity may increase rapidly.

Sensitivity Threshold

A Sensitivity Threshold is a point at which an assumption change begins to materially alter the prediction or a relevant predictive condition.

Thresholds may relate to:

value; probability; timing; operational state; system state; resource availability; boundary condition; external event.

Critical Threshold

A Critical Threshold is a sensitivity boundary beyond which the prediction may:

materially change;

become conditionally valid; become highly uncertain; lose methodology applicability; become infeasible; require reassessment.

Threshold Crossing $\neq$ Automatic Prediction Failure

It establishes a predictive governance condition.

Linear Sensitivity

Linear Sensitivity exists where assumption change produces approximately proportional predictive change within a defined range.

Example:

Every additional 1% cost increase reduces expected margin by approximately 0.4%.

ASNM may represent this relationship where methodologically justified.

Nonlinear Sensitivity

Nonlinear Sensitivity exists where predictive impact changes disproportionately across the assumption range.

Many real-world systems behave this way.

For example:

Server load may increase gradually without operational consequence until capacity approaches saturation, after which failure probability rises sharply.

Small Input Change $\neq$ Small Predictive Effect by Default

Discontinuous Sensitivity

Some assumption changes may trigger abrupt predictive transitions.

Example:

A regulatory authorization remains valid until revoked.

A small regulatory change may have little effect.

Formal revocation may immediately make an assumed commercial pathway impossible.

ASNM preserves discontinuities rather than forcing continuous representations.

Conditional Sensitivity

Sensitivity may exist only under another condition.

For example:

Fuel-price sensitivity may be high only where transport costs exceed a specified proportion of total product cost.

Conditional Sensitivity $\neq$ Universal Sensitivity

Contextual Sensitivity

The same assumption may exhibit different sensitivity across:

geographies; business units; populations; system configurations; market regimes; scenarios.

Sensitivity must therefore remain linked to predictive context.

Temporal Sensitivity

Sensitivity may change with time.

An assumption may have little importance early in the Prediction Horizon but become highly influential later.

Example:

A small financing shortfall may not affect operations this week but may materially constrain production six months later.

Horizon Sensitivity

The effect of an assumption may depend upon Prediction Horizon.

Low Short-Term Sensitivity $\neq$ Low Long-Term Sensitivity

For example:

Interest-rate changes may have limited effect on a seven-day sales forecast but substantial effect on a three-year investment forecast.

Boundary Sensitivity

An assumption may behave differently across predictive boundaries.

A labor-availability assumption may have minimal effect within one facility but high effect across an entire national production network.

Probability Sensitivity

An assumption change may materially affect the probability assigned to a prediction.

ASNM governs the sensitivity relationship.

PPUS later governs probability representation itself.

Probability Sensitivity $\neq$ Probability Governance

Uncertainty Sensitivity

Assumption weakening may increase uncertainty even where the central prediction changes little.

For example:

The expected output remains 1,000 units.

But uncertainty expands from:

± 50

to:

± 300 .

This is a material sensitivity effect even if the expected value remains unchanged.

Confidence Sensitivity

An assumption change may affect confidence in the prediction without directly changing the predicted outcome.

Stable Predicted Value $\neq$ Stable Confidence

Feasibility Sensitivity

An assumption may affect whether a predicted outcome remains realistically achievable.

Example:

A construction completion prediction may remain numerically unchanged while labor availability deteriorates sufficiently to make the forecast infeasible.

PFES later governs final feasibility state.

ASNM governs the sensitivity relationship.

Methodology-Applicability Sensitivity

Some assumptions affect whether Prediction Methodology remains applicable.

For example:

A methodology may assume a sufficiently stationary environment.

If regime change occurs, methodology applicability may deteriorate sharply.

This may be more important than change in the prediction's numerical output.

Interpretation Sensitivity

Assumption change may alter what a prediction legitimately means.

A forecast may move from:

expected outcome

to:

conditional scenario

without changing its headline number.

ASNM preserves this interpretive sensitivity.

Reliance Sensitivity

Assumption changes may alter the degree to which a prediction can legitimately be relied upon.

PCRS governs final communication and reliance.

ASNM may identify assumptions whose change can alter reliance conditions.

Sensitivity Propagation

Sensitivity may propagate through the dependency structure established by ADMM.

Example:

Supplier Financial Stress

↓

Supplier Continuity Assumption Weakens

↓

Component Availability Assumption Weakens

↓

Production Continuity Assumption Weakens

↓

Output Prediction Sensitivity Increases

ADMM maps the dependency pathway.

ASNM evaluates how changes through that pathway affect the prediction.

Direct Sensitivity

Direct Sensitivity exists where changing an assumption materially affects the prediction without needing another assumption to change first.

Indirect Sensitivity

Indirect Sensitivity operates through one or more dependency relationships.

Indirect pathways may still produce substantial predictive effects.

Indirect Sensitivity $\neq$ Low Sensitivity

Compound Sensitivity

Several assumptions may jointly create a predictive effect greater or different from their individual effects.

For example:

High energy prices

Low inventory

Transport disruption

may jointly affect production more severely than any condition individually.

Sensitivity Interaction

Assumption sensitivities may interact.

The effect of Assumption A may depend on the state of Assumption B.

Example:

Interest-rate sensitivity may become much greater where corporate leverage is already high.

Sensitivity of A $\neq$ Independent of B by Default

Sensitivity Amplification

Multiple dependencies may amplify the effect of assumption change.

A moderate upstream change may generate a large downstream predictive effect.

Sensitivity Dampening

Predictive structures may also absorb assumption change.

Redundancy, substitution, spare capacity, or alternative pathways may reduce downstream effect.

Dependency Change $\neq$ Equivalent Prediction Change

Sensitivity Concentration

A prediction may be disproportionately sensitive to a small number of assumptions.

This creates a sensitivity concentration profile.

The existence of many assumptions does not imply diversified predictive sensitivity.

Many Assumptions $\neq$ Diversified Sensitivity

Sensitivity Asymmetry

An assumption may affect a prediction differently depending on the direction of change.

Example:

Increasing production capacity by 10% may have little effect because demand is constrained.

Reducing production capacity by 10% may materially lower expected output.

Sensitivity Increase Direction $\neq$ Sensitivity Decrease Direction

Sensitivity Scenario

Where appropriate, sensitivity may be assessed using governed alternative states.

Example:

Assumption State A $\rightarrow$ Prediction State X

Assumption State B $\rightarrow$ Prediction State Y

Assumption State C $\rightarrow$ Prediction State Z

The purpose is not to replace simulation governance.

It is to govern sensitivity relationships.

SIMULOS® retains governance of formal simulation.

Single-Assumption Sensitivity

A prediction may be evaluated against one changing assumption while other relevant conditions are held sufficiently stable.

This can isolate local sensitivity.

However:

Single-Assumption Analysis $\neq$ Complete Predictive Sensitivity

Multi-Assumption Sensitivity

Where dependencies and interactions are material, multiple assumptions may need to be considered together.

This is particularly important where:

assumptions are correlated; dependencies are shared; thresholds interact; feedback exists.

Sensitivity Uncertainty

The sensitivity relationship itself may be uncertain.

Possible states may include:

Established

Estimated

Model-Dependent

Conditionally Established

Uncertain

Unable to Determine

Sensitivity uncertainty must remain visible.

Sensitivity Estimate $\neq$ Sensitivity Certainty

Sensitivity Confidence

Where applicable, systems may represent confidence in a sensitivity assessment.

This must remain distinct from:

prediction confidence; assumption confidence; probability.

Sensitivity Change

Sensitivity itself may change when:

Prediction Basis changes; methodology changes; system configuration changes; dependencies change; operational conditions change; Prediction Horizon changes; Predictive Boundary changes.

Therefore:

Historical Sensitivity $\neq$ Current Sensitivity

Historical Sensitivity State

A prediction reviewed retrospectively should preserve the sensitivity structure that applied when the prediction was formed or assessed.

Later discovery of stronger sensitivity must not silently rewrite the historical predictive state.

Later Sensitivity Knowledge $\neq$ Original Sensitivity Assessment

Sensitivity Reassessment

Sensitivity should be reassessed where material changes occur in:

assumption state; dependency structure; methodology; Prediction Basis; Prediction Horizon; Predictive Boundary; operational conditions.

Sensitivity Governance Sufficiency

Assumption Sensitivity is sufficiently governed when:

material sensitivity relationships are identifiable; direction is known where meaningful; sensitivity magnitude is represented where possible; relevant ranges are bounded; material thresholds are identifiable; nonlinear or discontinuous behavior is preserved where relevant; temporal and horizon sensitivity are considered; dependency-mediated propagation is visible; interactions among assumptions are identifiable where material; sensitivity uncertainty remains explicit;

current and historical sensitivity states remain distinguishable.

Governance Requirements

ASNM requires that:

1. material assumptions be assessed for predictive sensitivity where applicable;
2. dependency and sensitivity remain conceptually distinct;
3. sensitivity direction be represented where meaningful;
4. sensitivity magnitude be governed where material;
5. relevant sensitivity ranges remain identifiable;
6. tolerance ranges be represented where useful;
7. material thresholds be identifiable;
8. nonlinear sensitivity not be forced into linear representation;
9. discontinuous sensitivity remain visible;
10. conditional sensitivity not be represented as universal;
11. temporal sensitivity be considered where material;
12. horizon sensitivity remain visible;
13. probability sensitivity remain distinguishable from probability governance;
14. uncertainty sensitivity remain identifiable;
15. confidence sensitivity remain distinguishable from prediction confidence itself;
16. feasibility sensitivity remain distinguishable from final feasibility

determination; 17. methodology-applicability sensitivity be identified where material; 18. dependency-mediated sensitivity propagation remain traceable; 19. assumption interactions be governed where material; 20. sensitivity amplification and dampening remain visible; 21. sensitivity concentration be identifiable; 22. asymmetric sensitivity be preserved where material; 23. sensitivity uncertainty remain explicit; 24. historical sensitivity states remain reconstructable; 25. later knowledge not overwrite historical sensitivity assessments.

Governance Logic

ASNM applies the following governance logic:

Identified Predictive Assumptions

Governed Assumption Dependency Map

↓

Sensitivity Relationships Identified

↓

Sensitivity Direction Determined where meaningful

↓

Sensitivity Magnitude Assessed

↓

Applicable Range / Tolerance Range Established

↓

Thresholds and Critical Thresholds Identified

↓

Linear / Nonlinear / Discontinuous Behavior Distinguished

↓

Conditional / Contextual / Temporal Sensitivity Assessed

↓

Probability / Uncertainty / Confidence / Feasibility / Methodology Sensitivity Identified

↓

Dependency Propagation Effects Assessed

↓

Assumption Interaction / Amplification / Dampening Assessed

↓

Sensitivity Concentration Identified

↓

Sensitivity Uncertainty Preserved

↓

Historical Sensitivity State Preserved

↓

Governed Assumption Sensitivity Profile

↓

AMAM — Assumption Materiality Module

Where sensitivity cannot be sufficiently determined:

Assumption Sensitivity Governance Gap → Qualification / Additional Analysis / Scenario Examination / Explicit Uncertainty / Restricted Interpretation

Minimum Implementation Framework

A minimum implementation of ASNM must establish:

A. Assumption Reference

The Predictive Assumption being assessed.

B. Dependency Map Reference

The applicable dependency relationships established through ADMM.

C. Sensitivity Target

The predictive element potentially affected, such as:

Predicted Outcome / Probability / Uncertainty / Confidence / Feasibility / Methodology Applicability / Interpretation / Reliance / Other

D. Sensitivity Direction

Where meaningful:

Positive / Negative / Bidirectional / Non-Directional / Unable to Determine

E. Sensitivity Magnitude

At minimum:

Minimal / Low / Moderate / High / Extreme / Unable to Determine

F. Applicable Range

The assumption range over which the sensitivity assessment applies.

G. Tolerance Range

Where applicable, the range within which predictive impact remains limited.

H. Sensitivity Threshold

Any point at which predictive impact materially changes.

I. Sensitivity Form

Where applicable:

Linear / Nonlinear / Discontinuous / Conditional / Contextual / Temporal / Other

J. Propagation Path Reference

Material dependency pathways through which sensitivity may propagate.

K. Interaction Reference

Other assumptions materially affecting the sensitivity relationship.

L. Sensitivity Uncertainty State

At minimum:

Established / Estimated / Conditional / Uncertain / Unable to Determine

M. Historical Sensitivity State

The sensitivity state associated with the applicable prediction version and time.

Governance Outputs

ASNM may produce:

Governed Assumption Sensitivity Profile; Assumption Sensitivity Register; sensitivity-direction record; sensitivity-magnitude state; sensitivity-range record; tolerance-range record; Sensitivity Threshold Record; Critical Threshold Record; nonlinear-sensitivity record;

discontinuity record; conditional-sensitivity record; temporal-sensitivity profile; horizon-sensitivity profile; probability-sensitivity record; uncertainty-sensitivity record; confidence-sensitivity record; feasibility-sensitivity record; methodology-applicability sensitivity record; sensitivity-propagation map; assumption-interaction record; sensitivity-amplification record; sensitivity-dampening record; sensitivity-concentration profile; sensitivity-uncertainty record; historical sensitivity record; unresolved sensitivity requirements.

The primary governed output is:

Governed Assumption Sensitivity Profile

This becomes a principal input to:

AMAM — Assumption Materiality Module.

Critical Distinctions

Dependency $\neq$ Sensitivity

Dependency Presence $\neq$ Constant Sensitivity

Low Sensitivity $\neq$ Low Materiality by Default

High Sensitivity $\neq$ Automatic Criticality

Sensitivity at Range A $\neq$ Sensitivity at Range B

Threshold Crossing $\neq$ Automatic Prediction Failure

Small Input Change $\neq$ Small Predictive Effect by Default

Conditional Sensitivity $\neq$ Universal Sensitivity

Low Short-Term Sensitivity $\neq$ Low Long-Term Sensitivity

Probability Sensitivity $\neq$ Probability Governance

Stable Predicted Value $\neq$ Stable Confidence

Indirect Sensitivity $\neq$ Low Sensitivity

Sensitivity of A $\neq$ Independent of B by Default

Dependency Change $\neq$ Equivalent Prediction Change

Many Assumptions $\neq$ Diversified Sensitivity

Sensitivity Increase Direction $\neq$ Sensitivity Decrease Direction

Single-Assumption Analysis $\neq$ Complete Predictive Sensitivity

Sensitivity Estimate $\neq$ Sensitivity Certainty

Historical Sensitivity $\neq$ Current Sensitivity

Later Sensitivity Knowledge $\neq$ Original Sensitivity Assessment

Enterprise Application

ASNM enables organizations to understand which predictive assumptions can change significantly without materially affecting a prediction and which can destabilize it after only limited change.

This is critical in:

financial forecasting + AI prediction + supply chains + industrial operations + infrastructure + strategic planning + insurance + healthcare + markets + autonomous systems.

Without sensitivity governance, two assumptions may appear equally important simply because both are documented.

In reality:

one may tolerate substantial variation;

the other may sit immediately next to a predictive tipping point.

ASNM makes that distinction governable before AMAM determines final Assumption Materiality.

Use Case 1 — A Financial Forecast Looks Stable Until Interest Rates Cross One Threshold

A company forecasts that a major investment project will remain profitable.

The prediction assumes that borrowing rates remain within a reasonable range.

Analysts initially treat interest-rate changes as a simple linear risk.

Sensitivity assessment shows something different.

Between:

3% and 4.5%

the expected return changes only moderately.

Above:

5.2%

debt-service requirements cause available cash flow to deteriorate rapidly.

Above:

6%

the projected investment case becomes fundamentally different.

The critical governance question is:

Can an assumption be meaningfully governed when its effect is represented as gradual even though the prediction becomes radically more sensitive after a specific threshold?

ASNM identifies:

the tolerance range; nonlinear sensitivity; critical thresholds; direction and magnitude of change.

Dependency Presence $\neq$ Constant Sensitivity

Use Case 2 — The AI Forecast Keeps the Same Number While Its Uncertainty Explodes

An AI forecasting system predicts:

1,000 units of demand next month.

The prediction assumes that customer behavior remains comparable to recent history.

A major market disruption begins weakening that continuity assumption.

The central prediction remains approximately:

1,000 units.

At first glance, nothing appears to have changed.

However, the credible prediction range expands from:

950–1,050

to:

700–1,300.

The critical governance question is:

Can a prediction legitimately be described as stable merely because its central value has not changed when weakening assumptions have dramatically increased uncertainty around that value?

ASNM identifies the prediction's uncertainty sensitivity even though the headline prediction remains unchanged.

Stable Predicted Value $\neq$ Stable Predictive Condition

Canonical Boundary

ASNM governs the identification, direction, magnitude, range, threshold, form, propagation, interaction, uncertainty, and historical preservation of the sensitivity relationships between Predictive Assumptions and prediction outcomes, probability, uncertainty, confidence, feasibility, methodology applicability, interpretation, and reliance conditions. It does not govern assumption identification, dependency mapping itself, final Assumption Materiality, Assumption Change Governance, probability representation, final feasibility determination, Prediction Formation, Operational Reality, or prediction-level revision.

ASNM establishes:

how the prediction may respond when its assumptions change.

It does not determine:

whether that sensitivity is sufficiently important to make the assumption material or what action must follow when the assumption actually changes.

Canonical Closing Statement

An assumption does not become important merely because a prediction depends upon it. Its governance also requires understanding what happens when that assumption moves.

ASNM makes predictive sensitivity visible before assumption importance is determined.
