

About the Prediction Communication & Reliance Standard

What Is the Prediction Communication & Reliance Standard?

The Prediction Communication & Reliance Standard (PCRS) is the PGA™ Parent Standard governing how a Governed Prediction moves from prediction governance into communication, interpretation, and practical reliance.

A prediction may be methodologically legitimate when it is formed, yet become misleading when it is shortened, visualized, summarized, redistributed, interpreted outside its original context, or used to justify a decision stronger than the prediction itself supports.

PCRS governs that transition.

It ensures that a prediction does not acquire greater certainty, broader applicability, stronger authority, or greater decision significance merely because of the way it is presented or used.

Its foundational principle is:

A prediction must not become stronger in communication than it is in methodology.

Why Does PCRS Exist?

Prediction governance does not end when a prediction has been produced.

Many of the most consequential governance failures can occur afterward.

A probability may be communicated as certainty.

A conditional prediction may be presented without its conditions.

A forecast intended for one market may be applied globally.

A model output intended as decision support may become an automatic execution trigger.

A prediction market signal may be represented as population belief.

A feasibility-restricted prediction may be communicated as fully achievable.

A prediction with substantial uncertainty may be reduced to one precise number.

The prediction itself may not have changed.

Its meaning in use has.

PCRS exists to govern this gap between:

what the prediction actually establishes

and:

what people or systems may infer, communicate, or do because of it.

What Does PCRS Govern?

PCRS governs the lifecycle space in which a Governed Prediction becomes available for interpretation and use.

It governs:

Prediction Representation; communication context; material prediction qualifications; preservation of Prediction Object; preservation of Prediction Horizon; preservation of Predictive Boundary; methodology context; Prediction Basis and assumption context where material; Probability & Uncertainty representation; feasibility representation; collective-prediction qualifications; interpretation boundaries; intended-purpose alignment; prediction recontextualization; audience context; human and machine interpretation; Reliance Eligibility; reliance intensity; high-consequence reliance; automated reliance; overreliance; predictive misrepresentation; redistribution;

escalation conditions; communication state; reliance state; material reliance traceability.

PCRS therefore governs the transition:

Governed Prediction → Governed Representation → Governed Interpretation → Governed Reliance

Communication Is Not Neutral

Communication can materially change how a prediction is understood.

A prediction stating:

"70% probability under conditions A, B, and C over the next 12 months"

is not equivalent to:

"This will probably happen."

The second statement may remove:

the Prediction Horizon; conditionality; methodological context; uncertainty; relevant assumptions; Predictive Boundary.

The numerical prediction may remain unchanged while its communicated meaning becomes materially different.

Representation ≠ Underlying Prediction

Communication Compression ≠ Permission to Remove Material Meaning

Prediction Meaning Must Survive Communication

PCRS requires that material components of prediction meaning remain preserved or reliably accessible.

These may include:

Prediction Object What exactly is being predicted?

Predicted Outcome What event or state counts as the predicted result?

Prediction Horizon By when?

Predictive Boundary Where and under what scope?

Methodology Context By what governed predictive method?

Prediction Basis On what information or signals?

Assumptions What conditions must hold?

Probability & Uncertainty How uncertain is the prediction and what does its probability actually mean?

Feasibility Can the predicted outcome realistically be achieved under applicable conditions?

A shorter representation may still be legitimate.

But simplification must not materially change predictive meaning.

Probability Must Not Become Certainty

Probability communication is one of the most important PCRS governance areas.

A prediction of:

90%

does not establish certainty.

Nor does it establish that:

the predicted outcome must occur; uncertainty is negligible; feasibility is established; confidence is automatically high; reliance is justified in every decision context.

PCRS preserves the distinctions established elsewhere in PGA™:

Probability $\neq$ Confidence

Probability $\neq$ Certainty

High Probability $\neq$ Guaranteed Outcome

Numerical Precision $\neq$ Predictive Reliability

Prediction Feasibility Must Survive Communication

A prediction may be highly probable under a forecasting methodology while operational feasibility remains restricted.

Likewise, an outcome may be feasible while its predicted probability remains low.

PCRS prevents those concepts from being collapsed during communication.

Feasible $\neq$ Probable

Probable $\neq$ Feasible

A prediction classified as:

Conditionally Feasible

must not become:

Feasible

simply because a dashboard or executive summary removes the condition.

Collective Predictions Require Collective Qualifications

Where a prediction passed through CPGS — Collective Prediction Governance Standard, material collective characteristics may remain relevant to communication.

These may include:

source diversity;

Prediction Dependence; aggregation methodology; effective predictor structure; influence concentration; population representativeness; market structure.

A collective prediction should not gain stronger social meaning merely because it is easier to describe it as:

"the crowd believes"

or:

"the market says."

Market-Implied Probability $\neq$ Population Belief

Consensus $\neq$ Independent Consensus by Default

Participation ≠ Representation

What Is Prediction Interpretation?

Prediction Interpretation is the meaning assigned to a communicated prediction by a human, organization, AI system, autonomous agent, or downstream decision process.

Correct communication does not guarantee correct interpretation.

A prediction designed to answer:

“Is this project likely to finish before December?”

does not automatically answer:

“Should the organization invest €500 million in the project?”

The prediction may inform that decision.

It does not govern the entire decision.

Prediction Input ≠ Decision

Interpretation Boundary

PCRS establishes an Interpretation Boundary around the predictive claim.

The boundary defines what conclusions the governed prediction legitimately supports.

A prediction may support:

Outcome X is estimated to have a 65% probability within Horizon Y under Conditions A–C.

It does not automatically support:

Therefore Action Z must be taken.

Decision objectives, risk tolerance, policy, ethics, legal constraints, resource allocation, and organizational authority may belong to other governance spaces.

Intended Purpose

Predictions are created for purposes.

Examples include:

operational planning; risk assessment; investment analysis; scientific forecasting; resource allocation; scenario preparation; public communication.

A prediction created for one purpose may not remain equally legitimate when used for another.

Use Beyond Intended Purpose ≠ Automatically Legitimate Use

PCRS governs whether a changed use requires qualification, restriction, review, or escalation.

Prediction Recontextualization

Prediction Recontextualization occurs when a prediction is placed into a materially different context.

For example:

a prediction about one country may be reused globally;

a short-term operational prediction may be used for long-term investment;

a research forecast may be transformed into an automated production rule.

The underlying prediction may remain unchanged.

Its reliance context does not.

Same Prediction + New Context $\neq$ Same Reliance Meaning by Default

What Is Prediction Reliance?

Prediction Reliance is the extent to which a prediction influences an action, decision, prioritization, allocation, intervention, or automated process.

Reliance may range from:

Informational Reliance

to:

Advisory Reliance

to:

Decision-Support Reliance

to:

High-Consequence Reliance

to:

Automated Operational Reliance

PCRS does not assume that one prediction is appropriate for every reliance level.

Communicable $\neq$ Reliance-Eligible

This is one of the central distinctions of PCRS.

A prediction may be completely legitimate to publish.

That does not mean it is sufficient to:

approve a major investment; stop critical infrastructure; deny access to a service; initiate an automated intervention; make a safety-critical decision.

Publicly Available $\neq$ Operationally Actionable

Reliance Eligibility

Reliance Eligibility determines whether the governed state of a prediction sufficiently supports the proposed reliance context.

Relevant considerations may include:

prediction quality; methodology; uncertainty; assumptions; feasibility; intended purpose; Prediction Horizon; decision consequence; reversibility; operational criticality; degree of automation.

A prediction does not become reliance-eligible merely because it exists.

Prediction Exists $\neq$ Prediction Is Reliance-Eligible

Reliance Proportionality

The stronger the reliance, the stronger the required governance basis may need to be.

Using a forecast to prioritize which report an analyst reads first is fundamentally different from allowing the same forecast to automatically shut down industrial equipment.

PCRS therefore applies a proportionality principle:

Greater Reliance Requires Governance Proportionate to the Consequence of Being Wrong.

This does not guarantee predictive accuracy.

It governs whether the degree of reliance is legitimate given what the prediction actually supports.

High-Consequence Reliance

High-consequence reliance may arise in contexts involving:

safety; financial exposure; critical infrastructure; healthcare; public administration; autonomous systems; major organizational decisions; other materially consequential actions.

PCRS does not define sector-specific law.

It establishes the methodological requirement that predictive confidence must not be confused with authority to take consequential action.

High Probability $\neq$ Sufficient Basis for High-Consequence Reliance

Automated Reliance

AI systems and autonomous systems may consume predictions without a human reviewing every prediction individually.

This creates a particularly important governance boundary.

A prediction output may become:

Prediction $\rightarrow$ Machine Interpretation $\rightarrow$ Threshold $\rightarrow$ Action

PCRS requires that the existence of a prediction not automatically create execution authority.

Prediction Output $\neq$ Automatic Execution Authority

The governance of authority, execution, escalation, and autonomous behavior remains with the appropriate adjacent architectures.

Overreliance

Overreliance occurs when a prediction receives greater decision significance than its governed state supports.

Potential causes include:

automation bias; authority bias; consensus bias; numerical precision; source prestige; hidden uncertainty; omitted assumptions; visual simplification.

AI-Generated Prediction $\neq$ Superior Prediction by Default

Source Prestige $\neq$ Predictive Certainty

Consensus $\neq$ Certainty

Prediction Misrepresentation

A prediction can eventually be correct and still have been improperly communicated.

For example:

a 70% conditional prediction may be communicated as a certain future event.

If the event later occurs, the communication was still methodologically stronger than the underlying prediction justified.

Prediction Misrepresentation $\neq$ Prediction Error

PCRS governs the legitimacy of the communicated predictive meaning, not merely whether the eventual outcome happens to match the prediction.

Visual and Interface Representation

Prediction governance also applies to how information is visually prioritized.

A dashboard may display:

87%

in large text while placing major uncertainty and assumptions several screens away.

Technically, the qualification exists.

Operationally, the interface may still produce a materially stronger interpretation.

Visible Number + Hidden Qualification $\neq$ Balanced Prediction Representation

PCRS therefore recognizes that representation architecture can materially influence reliance.

Human and Machine Interpretation

PCRS applies to both humans and machines.

For humans, a prediction may be interpreted through language, graphics, rankings, or categories.

For machines, the prediction may be consumed through:

APIs; structured records; automated workflows; agent-to-agent communication; decision engines.

Machine-readable outputs must preserve sufficient context to prevent downstream systems from treating a governed prediction as a context-free numeric command.

Machine Readability $\neq$ Machine Interpretability

Prediction Redistribution

Predictions frequently move beyond their original publisher.

They may be:

quoted; embedded; summarized; translated; reposted; consumed through APIs; incorporated into another product.

PCRS establishes that redistribution does not create permission to remove material predictive meaning.

Prediction Redistribution $\neq$ Qualification Removal

Prediction Reflexivity

Communication may also change the world being predicted.

The lifecycle may become:

Prediction $\rightarrow$ Communication $\rightarrow$ Reliance $\rightarrow$ Action $\rightarrow$ Changed Operational Reality

For example, a prediction of a shortage may cause organizations to increase purchases, thereby contributing to the shortage itself.

Alternatively, a prediction of a failure may cause preventive intervention that stops the predicted outcome from occurring.

PCRS preserves the distinction:

Prediction Observation $\neq$ Prediction Influence

Prediction Influence $\neq$ Outcome Control

Prediction Influence $\neq$ Predictive Accuracy

Material changes created through communication or reliance can later become relevant to PMRS — Prediction Monitoring & Revision Standard .

What PCRS Does Not Govern

PCRS does not:

create Prediction Objects; determine predictive methodology; establish Prediction Basis; govern Predictive Assumptions; form predictions; calculate probability; determine uncertainty; determine Prediction Feasibility; establish Collective Prediction legitimacy; determine Operational Reality; assign decision authority; determine legal responsibility; revise predictions; determine outcomes; assess predictive performance.

Its governed space begins when a sufficiently governed prediction is ready to be represented, interpreted, or relied upon.

Cross-Architecture Boundaries

POPS governs Prediction Object, purpose, horizon, and boundary.

PMES governs Prediction Methodology.

PBAS governs Prediction Basis.

PAS governs Predictive Assumptions.

PFOS governs Prediction Formation.

PPUS governs Probability & Uncertainty.

PFES governs Prediction Feasibility.

CPGS governs Collective Prediction where applicable.

PCRS governs Communication & Reliance.

PMRS governs subsequent Monitoring & Revision.

POFPS governs Outcome & Performance.

PRCS governs Prediction Record & Historical Continuity.

ORA™ governs Operational Reality.

AGA™ governs accountability rather than prediction-reliance methodology.

AIG® and ASGA™ may govern behavior, authority, escalation, and execution when AI or autonomous systems act upon predictions.

Position Within PGA™

The complete PGA™ Governance Flow is:

Prediction Object & Purpose → Prediction Methodology → Prediction Basis → Prediction Assumptions → Prediction Formation → Probability & Uncertainty → Prediction Feasibility → Collective Prediction where applicable → Communication & Reliance → Monitoring & Revision → Outcome & Performance → Prediction Record & Continuity

PCRS occupies the point where the governed predictive object enters operational interpretation and use.

This makes it the boundary between:

what the prediction says

and:

what someone does because of it.

Why PCRS Matters

Prediction systems increasingly operate through dashboards, APIs, AI agents, automated alerts, recommendation systems, markets, and decision platforms.

The predictive model may be technically sophisticated.

Yet a single poorly governed transition from:

65% probability

to:

take the action

can bypass much of that sophistication.

PCRS makes that transition explicit and governable.

It allows organizations to distinguish:

Prediction $\neq$ Decision

Communication $\neq$ Interpretation

Communicable $\neq$ Reliance-Eligible

Probability $\neq$ Authority

Governed Prediction $\neq$ Automatic Execution Authority

What Organizations Gain

Organizations applying PCRS can establish a consistent methodology for determining:

how predictions should be presented; which qualifications must remain visible; what a recipient may legitimately infer; whether a prediction is suitable for a particular decision context; when reliance should be restricted; when human or governance escalation is required; when machine consumption requires additional context; whether a communicated prediction has become stronger than its governed basis.

The result is not merely better prediction communication.

It is a controlled bridge between prediction and action.

Use Case 1 — 82% Probability Becomes an Automatic Shutdown Rule

An industrial operator uses an AI prediction system to estimate equipment failure.

The system produces:

82% probability of component failure within the next 30 days.

The underlying prediction contains:

significant uncertainty; assumptions about operating temperature; a specific 30-day Prediction Horizon; a Conditionally Feasible maintenance pathway; no authority determination for shutting down production.

A downstream automation converts the prediction into:

Probability $>80\%$ $\rightarrow$ Immediate Production Shutdown

The critical governance question is:

Does an 82% governed prediction legitimately authorize automatic shutdown of an industrial process?

PCRS separates the predictive result from the reliance decision.

The prediction may be:

Communication Ready

while the proposed automated reliance may require:

Reliance Escalation Required

because:

Prediction Output $\neq$ Automatic Execution Authority

and:

High Probability $\neq$ Sufficient Basis for High-Consequence Reliance

The prediction remains legitimate.

The unsupported leap from prediction to autonomous action does not.

Use Case 2 — A Conditional Forecast Becomes a Public Claim of Certainty

A public forecasting organization publishes:

"There is a 74% probability that the energy project will become operational by December 2028, provided regulatory authorization is completed by March 2027 and grid integration is available by January 2028."

A media platform republishes the result as:

"Energy project expected to be operational by 2028."

The probability, conditions, and dependency structure disappear.

The critical governance question is:

Does simplifying the original prediction preserve its legitimate predictive meaning, or has communication transformed a conditional probabilistic forecast into a stronger unconditional claim?

PCRS identifies that the shortened representation materially changes the prediction.

The original statement contains:

probability + horizon + conditions.

The republished statement creates an apparent unconditional expectation.

PCRS therefore requires preservation or restoration of the material qualification.

Conditional Prediction $\neq$ Unconditional Prediction

Stronger Wording $\neq$ Stronger Prediction

A prediction must not become stronger in communication than it is in methodology.

Canonical Boundary

PCRS governs the legitimate transition from a Governed Prediction into representation, communication, interpretation, and reliance. It preserves the prediction's governed meaning, material qualifications, purpose, horizon, boundary, methodology context, uncertainty, feasibility, collective conditions, interpretation limits, reliance eligibility, and proportionality of reliance. It does not create, reformulate, validate, revise, or determine the eventual correctness of the underlying prediction, and it does not itself grant decision authority or assign responsibility for downstream action.

Canonical Closing Statement

Prediction governance does not end when the forecast is produced; it must survive the moment the forecast enters human or machine decision-making.

PCRS prevents probability from becoming certainty, information from becoming authority, and communication from silently expanding what a prediction actually establishes.

A prediction is not fully governed until its limits survive the journey from prediction to reliance.
